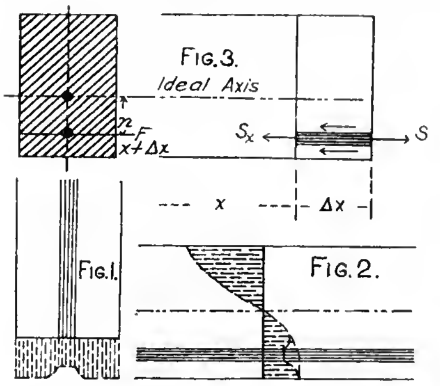
The theory of the resistance of concrete-steel beams is based on the assumption that the cross-sections of the beams remain plane after bending. This assumption simplifies the calculations essentially, but it does not actually hold true. Owing to the great difference in the values of the elastic moduli of steel and concrete, shearing stresses are induced near the steel. These stresses cause longitudinal displacements of the concrete mass around the embedded steel, which takes place even then, when sliding is prevented by the adhesive resistance. The original plane section thus becomes a warped surface with a funnel-shaped depression around the steel, as indicated in Figure 1. Even in homogeneous beams the longitudinal shearing stresses cause the section to be a curved surface instead of the assumed plane, and this is still more pronounced in the case of concrete beams. The modulus of elasticity of concrete varies with the stress on it, and concrete beams will already show a deformation of their cross-sections under the action of ordinary bending stresses. This deformation will be still further increased by the shearing stresses. If the beam is re-enforced by embedded steel the above mentioned funnel-shaped depression of the cross-section will be added to the deformation, as in Figure 2. This explains the fact that measurements of elongations taken during tests show an advance movement of the surrounding concrete relatively to the elongation of the steel. (See the results of two breaking tests with Hennebique solid floors, "Allgem. Bauzeitg.," 1901, No. 2.)

The above causes result in important errors in the common static computations so that the latter should be considered as approximations only. The effect of these errors are especially considerable in the results of deflections found by the ordinary computations. Owing to the longitudinal displacement, the deflections will be considerably greater than those given by the computations.

The value of the modulus of elasticity is of great importance in all static computation of concrete-steel structures, but this value is yet far from being established. The modulus of elasticity is dependent on the quality of the several ingredients, the proportions of the mixture and the age of the test specimen. It varies under increasing stress, decreasing more or less with increasing stresses and frequently dropping very much below the original value. A similar behavior is shown by other homogeneous materials, as steel, as soon as the stress passes the so-called elastic limit.

But while the elastic limit of steel is so high that it is and should never be reached by the working stresses, the same limit is so low in concrete that it is usually exceeded. The elastic limit of steel, for instance, may be taken at 35,000 pounds per square inch, and the modulus of elasticity at 29,000,000 pounds per square inch. Concrete on the contrary shows permanent deformations for very low stresses, and the same takes place in concrete-steel beams. In the latter case internal stresses between the embedded steel and the concrete will remain even after the removal of the external loads, if the adhesive resistance is sufficient to prevent sliding. Considere's experiments with reinforced concrete beams have shown that under repeated loads, alternating with complete unloading, the new loading caused elongations which were proportional to the stresses until the maximum of the preceding load was reached. But at the same time the modulus of elasticity kept on decreasing and every new loading which exceeded the previous limit caused a permanent elongation.

Bach's well known investigations furnish data on the numerical value of the coefficient of elasticity and its relation to compressive stress in concrete blocks of various proportions. But the information on these relations for simple tension and bending is very meager.



Considere found in his experiments on reinforced concrete beams that the concrete of the reinforced beam has the same coefficient of elasticity as simple concrete so long as the elongation does not materially exceed the amount which will cause rupture in the nonreinforced beam. If the load is increased to exceed this limit the coefficient of elasticity decreases almost to zero.

According to the above, concrete-steel structures, if stressed within the limits of elongation allowable for concrete, will have an elastic coefficient identical with the same value for simple concrete structures. Everything else being equal, the embedded steel will have none or a very inconsiderable effect on the value of the coefficient.

75-Ft. Monier Arch.—The well-known series of tests conducted by the Austrian Society of Engineers and Architects included the testing of a Monier arch of about 75 feet span. The results of this test are given in the "Report of the Committee on Arches," published in 1895. The concrete used for this arch was of Portland cement concrete of the proportion 1:3 by volume. The strength of this concrete was tested after hardening 35 to 39 days for compression and 4½ months for tension.

The tests gave for compression of cubes of about 4 inches, an average of 3,390 and 3,630 pounds per square inch for concrete set in air and water, respectively, and 2,850 and 3,175 pounds for prisms 3½ inches square and about 10 inches long. The moduli of elasticity were determined at average values of 5,180,000 and 4,660,000 pounds per square inch.

For tension the tests gave an average of 242 and 254 pounds per square inch. The moduli were found to average 5,690,000 and 6,220,000 pounds. During the test of the Monier arch careful observations of the horizontal and vertical deformations were taken and the modulus of elasticity of the whole arch determined from them. It was found to be 4,750,000 pounds. If this value of the modulus is compared with the values obtained from directly measured elongations of the same concrete, they will be found to be almost the same. It may be noted here that the modulus as found for the Monier arch has been determined from observations of the total deformations, disregarding the separation into elastic and permanent deformations. The modulus so obtained might be better termed the coefficient of deformation. In the determination of this coefficient the concrete section only was taken into account, neglecting the embedded steel. Evidently the steel did not much affect the value of the coefficient, and it may be concluded that the deflections remained independent of the presence of the embedded steel.

Prof. Melan's Tests.—In the "Jubilee Publication of the Technical High School at Brunn," 1899, Prof. Melan reports the following bending tests on concrete plates made by him. Twenty-three plates of equal dimensions but made of concrete of various proportions were tested at different ages. One of these plates, of 1:5 proportions, had an inverted T of steel, 1 9/16x1 9/16-inch, embedded in the lower side. The span was 1 meter, and the load was concentrated at the center. The breaking stresses for plates, 2½ to 3 months old, gave the average results:

Proportion.	
1:5	199 lbs. per. sq. in.
1:6	171 " " " "
1:8	128 " " " "

Plates one month old gave 152 pounds for 1:5 mortar and 142 pounds for 1:6. From the observed deflections the moduli of elasticity were deduced. The modulus of elasticity for 1:5 concrete was 938,000 pounds, and for the same concrete with steel embedded, as mentioned above, 955,000 pounds. Evidently here also the steel had little influence on the deflection of the plates.

Solid Floor Hennebique.—The writer reported in the "Allgem. Bauzeitung," 1901, on tests of solid floors of the Hennebique system. The results of elaborate calculations on the observations made during these tests are condensed in the following short table:

Load per sq. ft., lbs.	Coeff. of deformation, lbs. per sq. in.	Extreme fiber stress at center, lbs. per. sq. in.
102	2,490,000	199
215	1,990,000	292
323	1,422,000	328
430	1,025,000	342
610	600,000	356

As can be seen from an inspection of the above table, the coefficient of deformation decreased with increasing load, and the extreme fiber stress increased very slowly after passing the ultimate tensile resistance of the concrete. Exactly such a behavior of concrete-steel beams was directly proved by Considere's experiments, "Etude experimentale des propriétés du béton armé."

Value of Coefficient of Deformation and Its Effect on Results of Computations.—The question may be raised whether the coefficient of deformation or that of elasticity should be used in computations of concrete steel structures. The former corresponds to the total deformation, the latter, after elimination of the permanent set, corresponds to the elastic deformation and shows the purely elastic behavior of the specimen. Both coefficients represent numerical values of the ratio of the stress to the change of length caused by it per unit of length. According to the main assumption of the concrete-steel theory the change of length of the concrete must be equal to the change of length of the steel for the same layer. Both materials, hence, share uniformly in the deformations and all permanent changes of length must be common to both. This causes internal stresses in the member after the load has been completely removed. The permanent elongation of the concrete resists the elastic contraction of the embedded steel and induces thereby tensile stresses in the steel and compressive in the concrete. Each succeeding new load then causes stresses which have to be added to the existing internal stresses.

The above consideration leads to the conclusion that for the computation of concrete-steel beams the total deformations are determining and that the coefficient of deformation must therefore be used.

To illustrate the effect of the value of the coefficient of deformation on the calculated stresses in concrete-steel beams the same were computed for the above mentioned Melan plate with embedded T for different values of the coefficient. For a load of 2,200 pounds and a span of 1 meter the following stresses were computed for the plate, m denoting the ratio of the coefficient of elasticity of steel to the coefficient of deformation of concrete.

	Lbs. per sq. in.		
	m=10	m=20	m=30
Upper fiber stress.......	— 483	— 467	— 448
Lower fiber stress.......	+ 421	+ 352	+ 309
Greatest stress in steel..	+4,210	+7,060	+9,260

If it is assumed that concrete cannot resist tension and that it has to be wholly taken up by the steel, we get:

	Lbs. per sq. in.		
	m=10	m=20	m=30
Upper fiber stress......	— 690	— 561	— 505
Average stress in steel..	+10,600	+11,000	+11,400

Since the coefficient of deformation for the same plate has been found to be 955,000 pounds, the ratio m = 31 will be found to be correct for the given case. The stresses in the first of the above tables, based on the assumption of m = 30, will, therefore, most nearly represent the actual stresses. Of course, the assumption of a lower value for m will result in higher calculated stresses for the concrete and lower stresses for the steel.

Sliding Resistance.—The above-mentioned assumption of the theory of concrete-steel structures will hold actually true only when the sliding resistance of the embedded steel reaches the required amount. Should the resistance fall below it, sliding of the concrete along the steel will take place. Both materials will act independently, and the total resistance of the member will be materially reduced. To have a clear idea of the resistance of a concrete-steel structure an investigation of the sliding resistance is essential.

In Figure 3 let us consider the stress in the steel bar at the section X and at the section $X + \Delta X$ The increase of stress in the distance ΔX is:

$$S_{x+\Delta x} - S_x = \Delta S.$$

The steel tends to elongate under the action of this stress, but the sliding resistance of the surrounding concrete opposes this elongation with the surface a of the steel and the sliding resistance t per unit of surface; $\Delta S = at\,\Delta X$.

If ΔA_n is the difference in stress on the layer n between the sections, the theory of flexure gives

$$\Delta A_n = n\,(M_{x+\Delta x} - M_x)\ :\ I$$

Here I is the ideal moment of inertia of the section, or in other words, the moment of inertia of the newly formed composite section. Let F denote the area of the steel then

$$\Delta S = S_{x+\Delta x} - S_x = F\,m\,\Delta A_n.$$

If R_x represents the shear in section x at the distance n from the center of gravity of the steel from the ideal neutral axis

$$M_{x+\Delta x} - M_x = \Delta M_x = R_x\,\Delta x.$$

Substituting this expression in the expression for ΔA_n we get

$$\Delta A_n = R_x\,n\,\Delta x \div I,$$

and hence

$$\Delta S = R_x\,n\,m\,F\,\Delta x \div I = at\,\Delta x.$$

The sliding resistance t per unit of surface is thus given:

$$t = R_x\,m\,F\,n \div Ia.$$

For circular steel rods of diameter d

$$F = \tfrac{1}{4}\pi d^2;\ a = \pi d,$$

$$\text{and } t = \tfrac{1}{4}R_x\,mdn \div I.$$

The condition for required sliding resistance is then:

max. $t = \frac{1}{4}\,mdn \times$ max. $R_x \div I$, which equals or is less than q, if q is the greatest allowable sliding resistance.

Working Stresses.—The allowable working stresses on the materials of construction are determined by the principle that the probable loads which may come on the structure should not cause stresses which may endanger the continuous existence of the structure. It is well known that a beam will fail not only by a stepwise increase in the static load, but that also considerably smaller loads, if frequently repeated, will cause failure. The static load itself, therefore, does not furnish a sufficient indication of the safety of the structure. The latter is determined by the greatest stresses which frequently repeated will, according to experience, not endanger the structure. Considere's experiments on concrete-steel have shown that these greatest stresses are caused by frequent loads, which are only about two-thirds of the greatest static loads. The results are similar to those obtained by Woehler's experiments on wrought iron and steel. The consideration of the effect of frequently repeated loads becomes of special importance because of the probability that the sliding resistances along the embedded steel will decrease in time under frequently repeated loads. This result may be particularly expected if these loads are accompanied by shocks and vibrations. The decrease of the sliding resistances, again, means a decrease of the carrying capacity and, together with the same, of the factor of safety.

Another important consideration for the safety of concrete-steel structures is the possible danger which may arise from cracks in the concrete. The weakening of the section where the cracks occur results in a displacement of the neutral line as well as in sudden changes of stress. Under the action of movable loads the work of deformation which is induced at such points may easily lead to dangerous overstressing of the steel. Besides, cracks in structures exposed to the weather are always apprehensible because of the liability of moisture penetrating and freezing taking place. The writer is therefore of the opinion that the dimensions should be so chosen as to prevent such stresses as may cause cracks.

Aside from the above considerations in adopting unit working stresses, the inaccuracy of the method of computation and the effect of shocks and vibrations have to be considered. The writer advises making the allowable unit stress on concrete for compression one-seventh of the compressive resistance, the unit stress for tension due to bending one-half of the bending resistance of concrete, and the allowable unit sliding stress one-eighth to one-tenth of the sliding resistance.

The ratio m of the coefficient of elasticity of the steel to the coefficient of deformation of the concrete may be taken for thin plates as m = 20; for beams of greater depths m = 10. Steel should not be stressed to more than 14,200 pounds per square inch.

Since the writer believes it to be absolutely necessary to prevent any cracks, the tensile bending stresses should be determined first and in no case should they be allowed to exceed the allowable stress. For the computation of the embedded steel, however, the tensile resistance of the concrete should be neglected and the computation be made on the assumption of existing cracks at the section under consideration.

In all computations the probable load, in so far as it causes shocks and vibrations, should be increased by 20 to 50 per cent. and sometimes even more.

Christophe ("Le béton armé et ses applications," 1902) recommends m = 10, and gives two degrees of safety:

	Lbs. per sq. in.
1. *Safety of first degree.*	
Allowable compression on concrete.......	427
" " " steel	12,800
2. *Safety of second degree.*	
Allowable compression on concrete.......	711
" " " steel	21,400

He neglects in the computations the tensile resistance of concrete.

For the allowable shearing stress 21 to 35 pounds per square inch is assumed and the same values are also used for the sliding stress. All of the above values refer to stresses caused by flexure. The allowable stress for pure compression for the first degree is given as 355 pounds per square inch, for the second degree as 569 pounds. Long columns have to be figured according to a formula based on the well known Gordon formula. For columns of a square cross-section of side b and length l the coefficient by which the acting stresses have to be multiplied is given as $(1 + 0.0003l^2/b^2)$.

Data on Compression, Bending and Shear of Concrete.—The concrete used by the Committee on Arches of the Austrian Society of Engineers and Architects for the above mentioned Monier arch was of the proportion 1:3 and 4-inch cubes gave 3,500 pounds per square inch in compression. The second Committee on Arches of the same society tested prisms of concrete and masonry 20x20x39 inches. The concrete blocks of 1:5 proportion and 3½ months old gave an average compressive resistance of 1,800 pounds per square inch. Blocks of the same age and 1:8 proportion gave 911 pounds; and of 1:10 proportion 655 pounds. On the other hand, blocks reinforced by steel rods of the proportion 1:3½ and 3½ months old gave an average compression of 3,980 pounds per square inch. The embedded steel represented 8/10 per cent. of the concrete section. For m = 10, the ideal cross-sectional area would show the average compression of the concrete to be 3,700 pounds. The bending resistance of concrete was determined by tests made by Prof. Hanisch and J. Spitzer on specimens 6 months old of the following proportions.

Proportion.	Bending resistance.
1:3	597 to 711 lbs. per sq. in.
1:3½	470 to 569 " " " "
1:4	342 to 427 " " " "
1:5	228 to 284 " " " "
1:6	171 to 214 " " " "

For shearing resistance of concrete M. Teret, director of the laboratory of the Ponts et Chaussées at Boulogne, assumes that it is proportional to the compressive resistance. He deduced the ratio between the two to be 0.16 to 0.2.

The sliding resistance was found by Bauschinger to be 640 pounds per square inch, but more recent experiments have given results differing considerably from this figure. According to the experiments of Considere, the sliding resistance is very much influenced by the mixing of the concrete, especially by the amount of the water used. An increased percentage of water increased the sliding resistance considerably, and M. Considere found it at 157, 171 and 71 pounds per square inch, according to the percentage of water used in mixing. If the rolling scale was left on the steel rods, the sliding resistance amounted to 256 pounds. The concrete used for these experiments consisted of 300 kilos of cement and 1 cubic meter of sand and gravel in equal parts.

Extracts from Building Codes of German Cities for the Computation of Concrete Steel Floors.—Berlin: The static computation must prove that concrete-steel structures are able to carry 10 times the prescribed load, including their own weight, and that the steel alone is able to resist the tensile stresses.

Dresden: The static computations must be based on:

	Lbs. per sq. in.
Concrete in compression	356
Steel in tension and compression	12,500
Steel in shear	10,000

To prevent buckling of Hennebique columns the concrete of the same must have dimensions which will fully guarantee the avoidance of any dangerous stresses. The columns must therefore be figured not only for direct compression, but also for flexure. For the load acting centrally on the column the equation $I = 60Pl^2$, and for slightly eccentric action $I = 100Pl^2$ is to be used. In these equations I represents the least moment of inertia of the column sections in centimeters, P the load in metric tons and l the unsupported length in meters. If the eccentricity is comparatively great the resistance of the columns must be figured according to the rules of the theory of resistance as to eccentric action of forces.

Dusseldorf: The proportion of concrete must be such as to give after 28 days 2,140 pounds per square inch. The allowable compressive stress on concrete is 427 pounds and the tensile resistance, that is, the stress at which it is assumed the concrete will break, is 570 pounds per square inch. If a higher compressive resistance than that prescribed is proved to be available, a corresponding increase in working stress is allowed.

The highest working stress on the steel is 12,500 pounds for compression or tension and 10,000 pounds for shear. For wire rods 14,200 pounds and 11,400 pounds may be used. The stresses which may be ascribed to the steel are to be based on the ratio of the coefficients of elasticity of concrete and steel. The ratio $m = 10$ must be used. The embedded steel must be so designed that, in addition to the calculated tensile stresses, it shall also be able to take care of the shearing stresses in so far as the latter have not been provided for otherwise. Columns are to be designed according to the formula $I = 60Pl^2$. (See above).

Frankfort: Concrete-steel floors should carry their own weight and 10 times the prescribed load without any noticeable deformation. (See Berlin). Columns of concrete-steel are not permitted. The compressive stress on concrete must not exceed 356 pounds per square inch. All tensile stresses must be taken by the steel.

Hamburg: Allowable stress in direct compression 427 pounds, in compression due to bending 356 pounds, in tension zero. Allowable stress on steel, tension or compression, 12,500 pounds; shear, 10,000 pounds per square inch. Floors which are subjected to vibrations require an addition of 20 per cent. of the prescribed load. The reinforcing steel must be able to properly take care of the shearing stresses. In addition, the shearing stresses of the concrete section should not exceed 22 pounds per square inch. Columns to be computed as according to the Dresden rule.

Contract Troubles.

It is a rather marked characteristic of contracts drawn by capable engineers and architects, without the assistance of lawyers or reference to legal forms, that the requirements are stated in language so clear as to leave no question concerning the technical requirements laid down. Unfortunately when such a document reaches a lawyer for revision he is often tempted to cast it aside in utter disgust; it is wrong from beginning to end as a contract, although entirely satisfactory as a bald statement of what is required. The engineer or architect thinks that the lawyer is a windbag and the lawyer is sure that the man who drew up the alleged contract is an imposter. It is the lack of appreciation by the man of one profession of the needs of the other which produces this unfortunate condition. It is accordingly of interest to notice some suggestions to engineers and architects drawing contracts, which were recently made by Mr. John C. Wait, M. Am. Soc. C. E., assistant corporation counsel of New York City, who is engaged almost exclusively in revising the many contract forms needed by the municipality. The full paper by this engineer-lawyer will be found in the "Transactions" of the Association of Civil Engineers of Cornell University, and it deserves careful study.

One common reason why engineers' or architects' contracts for city work cannot be used, this author states, is their lack of conformity with the statutes, charter provisions and ordinances governing such contracts. Laws and ordinances are framed in terms and phrases which the caution and experience of a lawyer teaches him to repeat in his contracts. If the requirements of the charter be couched in lengthy and round-about expressions peculiar to legislators, the lawyer employs the same verbose language in his contract, feeling that if the courts have some time construed the statute, that the same interpretation would apply and must apply to the terms of his contract; and that he thereby limits or extends the powers and duties described in the contract to the same extent as was intended by the legislature and as interpreted by the courts. The engineer, not having before him the ordinances, laws or charter, and not knowing their language, sneers at the peculiar, extraordinary or inapplicable language of the contract and attributes it to the ignorance of the lawyer, without knowing or considering its source.

The engineer seeks to abbreviate the contract, to accomplish which he would combine clauses required by different provisions of the charter, ordinances or laws. As an example, in municipal contracts it is required by the ordinances and by the general village laws of the State, and by a special act of the legislature, and by the charter of The City of New York, that no person, public officer, school commissioner, or any officer of any bureau, department, etc., shall be interested directly or indirectly in any contract for public improvements or supplies. The language is different in each law and the questions arise whether or not they should all be inserted in the contract, or whether a provision should be made which should embody the purpose or intent of all four, or whether that provision passed expressly for the city in its charter alone should be utilized. These provisions being required to be inserted, the lawyer would insert them in the precise language of the statute, as nearly as may be, while the engineer would express in his own language the intent of the legislature as he might interpret it. These are differences in methods which make the disparity between contracts prepared by lawyers and those prepared by engineers.

Another feature of an engineer's contract is his apparent desire to extend his power over the contractor and to reserve to himself power without regard to their rights. The chief object of putting work into the hands of an independent contractor is to avoid the responsibility that attaches to an employer for the acts and negligence of his servants. By extending the powers of an engineer or architect the contractor is frequently made a servant whereas the owner intended that he should be an independent contractor, Mr. Wait points out; the test being whether or not the owner maintains the direction and control of the contractor. By reserving to the engineer the control of the contractor, the contractor becomes a servant, and the owner becomes responsible for the acts and the negligence of the contractor and his servants.

Another objection to extending the powers of the engineer, making him an arbitrator to determine all questions, is that it ousts the courts of their jurisdiction to determine disputes between litigants, which is guaranteed to the constitution and renders the provision of the contract providing for the engineer's determination of questions void, as being against public policy. Contracts are frequently drawn which make the determination of the engineer conclusive upon the contractor only; and further provide that the owner shall not be precluded from showing the correct amount and character of the work done, etc. Such contracts are construed either as not binding, or as binding upon both parties as if the decision of the engineer was made final and conclusive upon the owner as well as the contractor. The clause that the owner shall not be precluded from at any time showing the true amount and character of the work done is interpreted to mean that the city may dispute the determination of the engineer when the parties have not had the benefit of his honest judgment for which it is assumed they stipulated. Therefore, it is held by the courts that the owner, city or contractor may question the engineer's decision when it is made in bad faith or when there has been such a gross error as to necessarily imply fraud. These are conditions the proof of which will upset the determination of the arbitrator in any case, so that the extra efforts on the part of the engineer to protect the interests of his employer are without avail.

The provision for liquidated damages is another rock upon which engineers' contracts are wrecked. The clause for liquidated damages is regarded by some engineers as a club with which to menace the contractor and to urge him to a speedy and satisfactory completion of the contract. In their efforts to wield so large a club, i. e., by making the damages so large, they show to the court that the so-called liquidated damages are in truth a penalty, which it is the avowed policy of the courts not to enforce against the contractor, in whole or in part. Moreover, if the amount stated be damages strictly, assessed for the purpose of indemnifying the owner or city for actual losses by what authority can the engineer release the contractor from the obligation to make such losses good? The engineer, in his attempts to coerce the contractor, betrays to the court and the jury the true reason for inserting the clause, viz.: to provide for a penalty or forfeiture.

The relation of the bid or proposal, the contract, the specifications and the plans, is frequently not well understood and is discussed by Mr. Wait at length. The terms bid, contract, specifications and plans, as designating instruments or documents separate and distinct from the contract, are misnomers. The "contract" should embody all these. If there be conflict between the parts, it is simply an ambiguity which is to be cleared up by the application of general rules for the interpretation of instruments, the aim and object of which is to ascertain the intention of the parties. If the intention be known, it will prevail. If there be no ambiguity, no evidence of the intention of the parties will be admitted by the court, and no evidence will be admitted of understandings, conversations or terms arrived at previous to or at the time of making the contract. The written contract will be presumed to contain all the terms of the agreement.

The specifications are regarded generally by engineers as a place to describe the materials of construction and the quality of workmanship required. They should enumerate, carefully describe and embody the plans, and together these should give a full and complete description of the materials and work to be furnished and of the structure to be erected. Together they should contain all the dimensions, instructions and directions necessary to secure the result sought to be accomplished. They should definitely describe the site of the structure, and usually should define the process of manufacture of materials, and the finished materials of construction, not only positively as to good properties, but negatively by naming the defects that they shall not contain. They should provide for inspection and tests at the mills and shops, and for inspection during erection, and every type of work should be described in sufficient detail to enable the builder to complete the structure without further directions from the engineer or superintendent.

The several parts of a contract must be connected. If they be not physically joined together, then they constitute different documents, unless there be a clear reference in one to the others. Without such reference one cannot be read into the other so as to define or modify the obligations assumed by the parties. Without it parol evidence cannot be introduced to identify the parts of a contract.

A requirement frequently made by architects is that the specifications and drawings shall remain the property of the architect, and that they must be returned to him before the contractor shall be entitled to his final certificate and payment for work done. This stipulation is unreasonable to the contractor, because, if insisted upon, it takes from him evidence which properly belongs to him and is essential to the establishment of his rights to recover for regular or extra work done and materials furnished. The plans and written instructions and directions of the architect are the contractor's best evidence of what he has been required to do, and he is justified in refusing to part with such evidence. It is at least doubtful if the architect can claim any ownership to specifications and plans which he has prepared as against the owner who has employed him and paid him therefor, though he may have incorporeal rights in the designs and creations which the drawings and specifications embody.

The engineer should see that his specifications and plans and the lawyer's contract are not in conflict. This will occur when the contract and specifications are prepared by different persons of different professions. The duty of the court is to determine the intention of the parties, and, in order to determine that intention, the entire contract will be considered, not only in the construction of any part, but in the interpretation of the whole. If compatible with the rules and maxims of the law, the mutual intention will prevail. The court will, so far as possible, put itself in the position of the parties at the time the contract was executed, and will consider the condition and circumstances under which they assumed the contract obligations. The conduct of the parties and the practical interpretation which they themselves have given to the contract will be given their proper influence if the intention be not clear as expressed.

Other things being equal, the contract is usually held to prevail over the specifications. The former is a more ceremonious undertaking, and usually defines the obligations of the parties. On the other hand, the specifications and plans are descriptive of the work and the manner in which it is to be performed, and are almost always subject to change or modification, as conditions and circumstances attending the performance of the work may arise. With regard to plans, it may be said that they are not easily carried about; to make alterations in them requires drafting instruments and scales; while the specifications may be changed quickly by a pencil or a writing pen, which are always at hand. It is therefore suggested that the specifications would probably be controlled ordinarily by the plans, so far as representing the original intention of the parties, but as any part of the contract is subject to modification by the parties, alteration in the specifications might control so far as the execution of the work was concerned, whatever might have been the original intention of the parties.

Another circumstance to be considered in the interpretation of clauses which are in conflict is that the courts usually construe stipulations most strongly against the parties who used or prepared them. This rule has been applied generally, except where the government or public are the parties, in which case it is usually held that the meaning will be adopted which is most favorable to the government or public, holding that the interest of the public should be protected, because there is nobody who has the interest in the public's welfare that a person has in his own.

It is a practice among lawyers to provide in their contracts that the materials and work shall be the best and that the whole job shall be completed in a first-class, thoroughly workmanlike manner, this being the wish of the owner. The engineer or architect, on the other hand, is trying to keep within the sum available for the job and is describing the work and materials to meet the money in hand. The result is that what the contract requires, the specifications do not provide. The question arises as to whether the contractor is excused from making a first-class, workmanlike job if he has completed it according to the specifications and plans.

An undertaking to construct a piece of work is an undertaking to do it well and in a workmanlike manner, whether this is expressly stipulated or not, but if the owner specified the materials, workmanship or the manner in which the structure is to be erected, and if, after completion, it proves to be defective and does not fulfill the purpose for which it was intended, then the loss falls upon the owner. Anybody who undertakes to erect a structure impliedly warrants that he is reasonably skillful in his trade or calling, and that the materials he uses should be suitable for the purpose for which they are used. The fact that the price to be paid is grossly inadequate does not excuse the contractor from fulfilling his undertaking to do a thoroughly workmanlike job.

The court sometimes distinguishes those cases in which the contractor is merely to build according to plans and specifications from those in which he is to completely finish and deliver up a structure ready for use. If the contractor undertakes to deliver a structure complete, the courts frequently hold that such an undertaking is a guarantee that the plans and specifications are sufficient, and that by undertaking to complete and deliver a finished structure the contractor adopted and approved of the plans and specifications. This was held where a building was built according to various detailed plans and specifications, and, owing to the latent condition of the soil, the foundation settled. The court held that the contractor, having agreed to completely finish the building, fit for use and occupation, that he was bound by that covenant. So, too, where a contractor was to construct a well for a certain sum, according to specifications which called for a curb of a certain shape and size, to be made of timber and planking of a prescribed size and quantity, it was held that the contractor could not recover for the work and materials lost by the caving in of the well before completion, notwithstanding it was due to the weakness of the curb specified.

When a structure is to be built according to specifications and to the satisfaction of the engineer, it may be doubted if his acceptance will hold unless the work has been done according to the contract. Much must be left to the engineer's discretion and judgment, which is for his own honest determination, but so far as the contract and specifications show an evident intention to limit the engineer's discretion and to fix the quality of the work and the degree of its perfect execution, so far must the engineer follow the specifications and instructions. He may decide whether work has been executed in a workmanlike manner, if materials are of the kind required, but it cannot be contended that the engineer can accept something totally unlike that which is called for, even though it is substantially built and for all practical purposes as good or even better than the structure specified in the contract. An acceptance by the engineer of a different class of work or of inferior materials will not bind the owner nor will it relieve the contractor from his agreement to perform according to plans and specifications.

Often the owner insists that work shall be completed to his satisfaction, and is indulged by providing for it in the contract. If the specifications have been prepared, or a certain result is to be obtained which has been defined and described, and the work be completed according to such specifications, or in such manner as to accomplish a certain definite result, the question arises if the owner must be satisfied. If the contractor has undertaken to do the work to the full satisfaction of the employer, he cannot be considered to have fulfilled his contract obligations until he has completed the work to the satisfaction of the employer. If the structure to be erected be one that cannot be removed and be a benefit to the owner or employer, it is unreasonable and unjust that the contractor should be denied a recovery for the reasonable value of his work and materials, or at least for such an amount as the owner or employer has been benefited. The courts are therefore in sympathy with a recovery to the contractor in such cases. The case of work upon chattels and manufactured articles is distinguished from that of work upon buildings or structures. In the former case, the courts maintain that the contractor can virtually be placed in statu quo by the return of the chattel or manufactured article which does not suit the employer, and therefore the courts usually hold that no recovery can be had. But, when the work has been the erection of a bridge, or a piece of machinery or a house, which, by virtue of its permanent character has become attached to the land of the owner, the courts hold that if the work has been done according to the plans and specification prepared and submitted by the owner, that it should be and must be to his satisfaction, and that therefore he must recompense the contractor. The courts hold in such cases that work need be completed only to the owner's reasonable satisfaction.

A provision that is often omitted in contracts, and which is of considerable importance at times, is one to require that extra work or "extras" shall conform to the specifications and plans. Clauses which provide for the engineer's determination and acceptance in regard to materials and work done under the contract, have been frequently and generally held not to apply to extra work. This question is rarely raised because it is probably a foregone conclusion among contractors and engineers that it was the intention of the parties to have materials employed in extra work conform to that work which is expressly provided for in the contract. The manifest intention of the parties is to have good, substantial work done and to employ materials of good quality and make; and in order that the job or structure should conform throughout to good workmanship, it is a natural inference that the specifications should be followed in providing and furnishing extra materials and work, as for the work specially provided for; but this conclusion is perhaps no stronger than that it was intended that the engineer should determine questions in regard to extra work as well as questions in regard to regular work.

Electro-Pneumatic Control of the Moon Island Sewage Reservoir, Boston.

The sewage of the Boston Main Drainage system flows by gravity to a point on Dorchester Bay known as the Cow Pasture. Here it is at a depth of 14 feet below low water, and is pumped through a 90-inch tunnel under Dorchester Bay to Squantam and thence flows to Moon Island, where it is stored in four reservoirs having a total capacity of 50,000,000 gallons, from which it is discharged into the outer bay at low tide. The gates regulating the flow of the sewage into and out of the reservoirs are operated by a turbine, which in turn derives its power from the flow of the sewage either into or out of the reservoirs.

As the discharge from the reservoirs is at a low velocity and at the same end of the tanks as the inlet, a considerable amount of sediment is left in the bottom. To prevent the accumulation of this deposit, there was built at the further end of each tank from the outlet, a gate chamber from which, after the tanks have been emptied, raw sewage is discharged at a comparatively high velocity, thus washing all the sediment out through the discharge gates. These flush gates being necessarily at quite a distance from the shaft which runs the main inlet and outlet gates the power from the turbine could not be directly utilized in their manipulation. A system which would make use of the energy supplied by the turbine and be admissible of carrying the power thus generated to a considerable distance for application is found in the use of compressed air controlled by electricity, as arranged in the Westinghouse electro-pneumatic devices, some slight alterations from the standard form in use on railways being necessary to suit the special application here. An interesting description of this installation was given some time ago in "The Railway and Engineering Review," from which the following account has been taken:

The essential features embodied in this installation are: First, the operation of one to four gates located at a distance of from 950 to 1,500 feet from the center of control; second, a power sufficient to operate under varying heads of flow, causing a variance of power required; third, a means of control for each or all gates, by which any one or all may be opened or closed; fourth, an indication of their position, closed or open or in motion.

Operating power is supplied by an Ingersoll-Sergeant air compressor driven from the shafting connected to the turbine. It has a capacity of 69 cubic feet per minute, at a speed of 120 revolutions. From the receiving tank, located in the engine house with the compressor, a 1½-inch air pipe is carried along the side and end of the basins, and from it ¾-inch pipes branch into the four houses erected over the flush gates, being there connected to the operating mechanism. All pipe is carried under ground in hard pine trunking and auxiliary reservoirs are located in manholes at points of connection to the houses and also at the exit of the main air pipe from the engine house. These collect any moisture or sediment which may be contained in the air pipe and carried along by the air, and by means of blow-off cocks may be emptied at any time, thus insuring a supply of clean, dry air at the point of appliance.

The flush gates are of iron and are raised vertically through grooves in a frame fastened against the granite wall, friction being minimized by the use of composition metal plates on the sliding surfaces; and to insure a minimum leakage they are forced tight against the frame, when down, by wedges attached to the four corners of the gates, the weight of the gate being sufficient to cause the wedges to perform their function. Connected to the gate is the piston rod of a 4 foot by 10-inch vertical cylinder or ram and by the introduction of air at sufficient pressure above or below the piston head, the piston is forced up or down, thus opening or closing the gate. Pipes of ¼-inch diameter are tapped into the top and bottom of the ram and are carried to an electro-pneumatic valve mechanism, placed on an iron shelf against the side of the building.

In the engine house a cabinet containing 15 cells of Edison-Leland battery, the only source of electrical energy required, is used for the push-button machine by which the operation of the gates is controlled and in which the indication is shown. The circuits required for the control of the gates and the indication of their position, are carried on two waterproof wires for each gate, the air pipe affording ample means of common return. All wires are run underground in the same trunking with the pipe, but in a separate groove, and as an extra precaution against injury by the action of sewer gas, both are covered with pitch poured over them while hot.

From the machine a 10-wire cable (two wires being spare) is carried to gate house No. 4; from house No. 4 to house No. 3 a six-wire cable is run; from house No. 3 to house No. 2 a four-wire, and from house No. 2 to house No. 1 a two-wire, the cable in each of the houses being brought to a terminal board. This is done to facilitate the tracing and location of any trouble which might occur, all wires being in short stretches.

In the gates houses the wires are connected to the magnets controlling the motion of the slide valve, which, by assuming either of two positions, admits air into the pipes to the ram for an upward or a downward throw; and by the use of a mechanical arrangement of gears, connected by a wire run over pulleys to a light rod which projects through the top of the ram, and which, being a continuation of the piston, travels with it, a new circuit is formed, remaining constant while the gate is in operation and ceasing when the gate reaches either extreme position, up or down. By this latter circuit indication is made in the machine in the engine house, where, during the movement of a gate a corresponding marker shows red, but upon the completion of the stroke and a consequent ceasing of the current, the marker is released and assumes a new position by gravity where it shows white.

The controlling buttons in the machine are in pairs, one above the other, as in railway switch operation, and as the upper one is pushed in, setting the indication arm and making contact which forms the circuit for raising the gate, the lower one is forced out and in this way the position of the buttons indicate the position of the gate.

The two pipes from the slide valve to the ram are used alternately as a passage for air applied in the ram or exhausted from it, the exhaust reaching the open air through a small chamber which is part of the valve. On the up-stroke, for opening the gate, air is admitted to the bottom of the ram, and as the piston is forced upward the air above is exhausted through the pipe connecting the top of the ram with the valve mechanism. On the down-stroke, for closing the gate, the operation is reversed, the top pipe acting as supply and the bottom as exhaust.

The gates weigh 1,500 pounds and this, when the weight of the piston, the friction in the ram and on the sliding surfaces is added, will be equal to about 2,000 pounds to be lifted. With no head in the sewer the gate rises at 15 pounds pressure, and with extreme head at 35 pounds.

On the down stroke, the weight of the gates, etc., would have a tendency to cause a rapid fall if the pressure supporting it was at once discontinued. To obviate this difficulty a swing check valve having a small hole drilled in the seat, is so inserted in the pipe from the bottom of the ram that pressure to the ram causes a full opening, but exhaust causes it to close, the drilled hole allowing but a small escapement of air, which, by its slow passage, forms a cushion in the ram and offers sufficient resistance to prevent any sudden fall. Shortly before the time of flushing, the compressor is thrown into service and in about 15 minutes enough air (a gauge pressure of 35 to 40 pounds) is stored in the receiving tank and pipe line for the operation of all the gates. The compressor may then be shut down until air is again wanted for another operation.

During the ten years of the operation of this plant, no changes have been made except the enlarging of the basins to twice their original capacity, as described in The Engineering Record of November 4, 1899, this enlargement making necessary the system of flushing which has now been installed for about 9 months. Storage of the basins takes place for 20 hours each day and 4 hours is allowed for discharge, this being ample time, for the sewage passes out at the rate of 1,000,000 gallons per minute, and the basins may be emptied in about 50 minutes. During discharge, sewage is noticeable for about two miles down the harbor, but in a short time after closing down it is so thoroughly mixed with the salt water that it is entirely lost to observation.

Electrolysis of water mains on the Cob Dock at the Brooklyn Navy Yard is causing serious trouble.

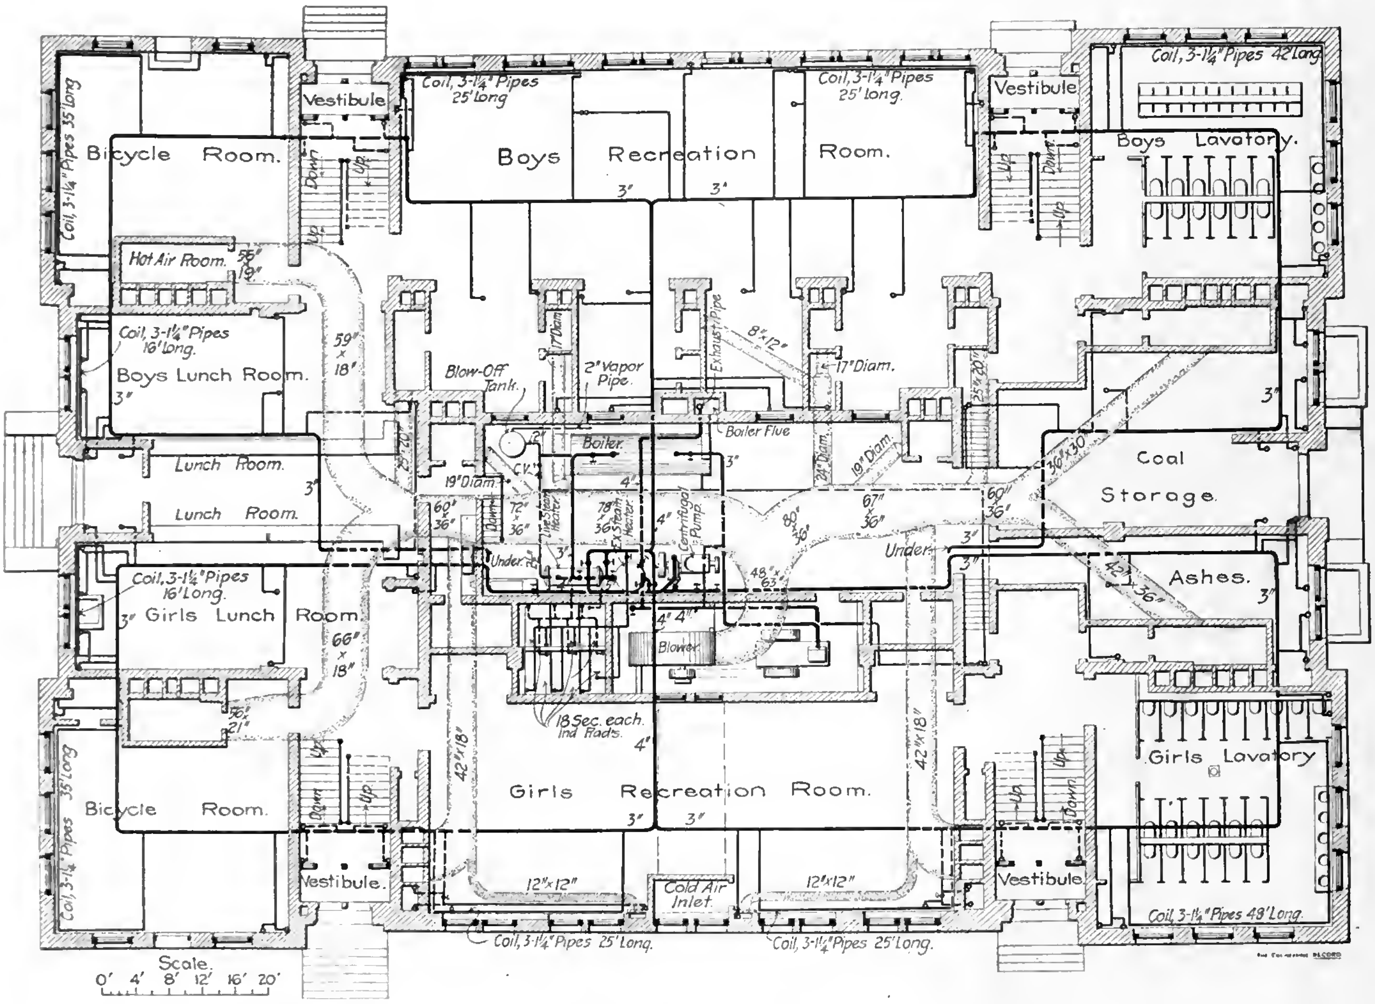
Ventilating and Heating the Worcester, Mass., High School.

The City of Worcester, Mass., has recently completed a new high school building which is warmed by hot water under a forced circulation. The system is of the direct radiation class, with the air supply for ventilation only. The air is, of course, tempered, indirect hot-water radiators being used; and an exhaust as well as a plenum fan are employed to circulate the air. The water warming apparatus comprises two heaters, one to utilize all exhaust steam without back pressure, and the other, to receive live steam when the supply of exhaust is insufficient. For the generation of steam, a single boiler has been relied on. The apparatus is arranged compactly with reference to easy control, and both the air and the water are distributed in an interesting manner.

The building is a three-story and basement story, where it has a gallery, and it has a seating capacity of 1,200 persons. On this plan may be pointed out the distribution of flues for the air system between rooms and corridors and the unusual location of wardrobes economizing the spaces between flues. As stated the assembly hall occupies space in the second story, which is arranged like the first story, with school rooms on three sides, separated from the assembly hall by corridors. The third floor consists largely of laboratories, which are arranged on all four sides, with a drawing room in the center lighted by overhead skylights in the roof. Four stairways rise through the building.

The ventilating system has been designed to supply and exhaust about 40,300 cubic feet of air per minute. The total number of seats in the school rooms is 1,240, so that the per capita supply of air on this basis is about 32.5 cubic feet of air per minute, 2.5 cubic feet charged through a system of ducts and flues to openings in the rooms. The tempering surface consists of Bundy Newport indirect radiators supported in two tiers on tee irons and pipe standards, comprising altogether 12 stacks of 18 sections each, and aggregating 4,320 square feet. As the blower is designed to handle 40,330 cubic feet of air per minute, 560 cubic feet of air are passed per hour per square foot of the tempering stacks.

The fan is a full-housed, steel-plate blower made by the American Blower Company, of Detroit, and has a wheel 8 feet in diameter and a discharge outlet 53.5 inches square. It is driven by belt from a 10x10-inch horizontal center-crank piston valve engine built by the blower maker, and under ordinary operation is depended on to furnish about 40,330 cubic feet of air per minute. The air is delivered through a top horizontal discharge and into the duct work which, as usual, is of galvan-



PLAN OF THE BASEMENT.

structure, 109x156 feet in plan, and contains 37 rooms, exclusive of a large assembly room and the basement. It has six entrances, four giving access to both the basement and the first floor. The plans of the basement, first floor and attic are shown in the accompanying drawings. As indicated on the plan of the basement, the rooms of that story are only occupied for short periods and are not provided with special means for ventilation, except the main lavatories from which separate vent passages are furnished to prevent a diffusion of the air from those rooms into the rest of the building. The apparatus for heating and ventilation has been located in the center of the basement with space for coal storage and for ashes at one end.

In the first story, as shown, are a number of school and teachers' rooms and an assembly hall. The latter extends through the second above the State requirement. In the case of assembly hall air is delivered through eight fresh air openings aggregating 48 square feet in gross area; with a velocity of 400 feet per minute through the openings, on the basis of the gross area stated, 32 cubic feet of air can be supplied per minute per person with 600 people in attendance. This means with 1,200 people, the full capacity of the hall, that 15 cubic feet are delivered per capita per minute. On account of the short periods of occupancy, it was not considered justifiable to make provision for greater air supply.

The air for the ventilating system is received through basement windows in the front of the building into a cold-air chamber walled off from the girls' recreation room, and is then carried in an underground passage to the tempering chamber. From the tempering stacks it is received by the blower and then discharged ized iron suspended from the ceiling. The duct system, however, is comparatively simple, in that it consists in a general way of large ducts which deliver to hot-air rooms, so called, spaces bricked off at the foot of different clusters of flues. Dampers are provided for directing the air to the hall flues, when desired. The individual supply to the rooms is taken from these points and the air flows into the room through an opening in the inside wall of the room, 8 feet from the floor. Over the room opening is fitted a bronzed wire screen, and to control the air flow each supply flue has a balanced damper in it, with a rod extending through the brick wall into the room, fixed permanently to equalize the distribution of air throughout the system. At the room opening there is a deflector to control the direction of flow. A velocity of 2,000 feet per minute is allowed in the main ducts.

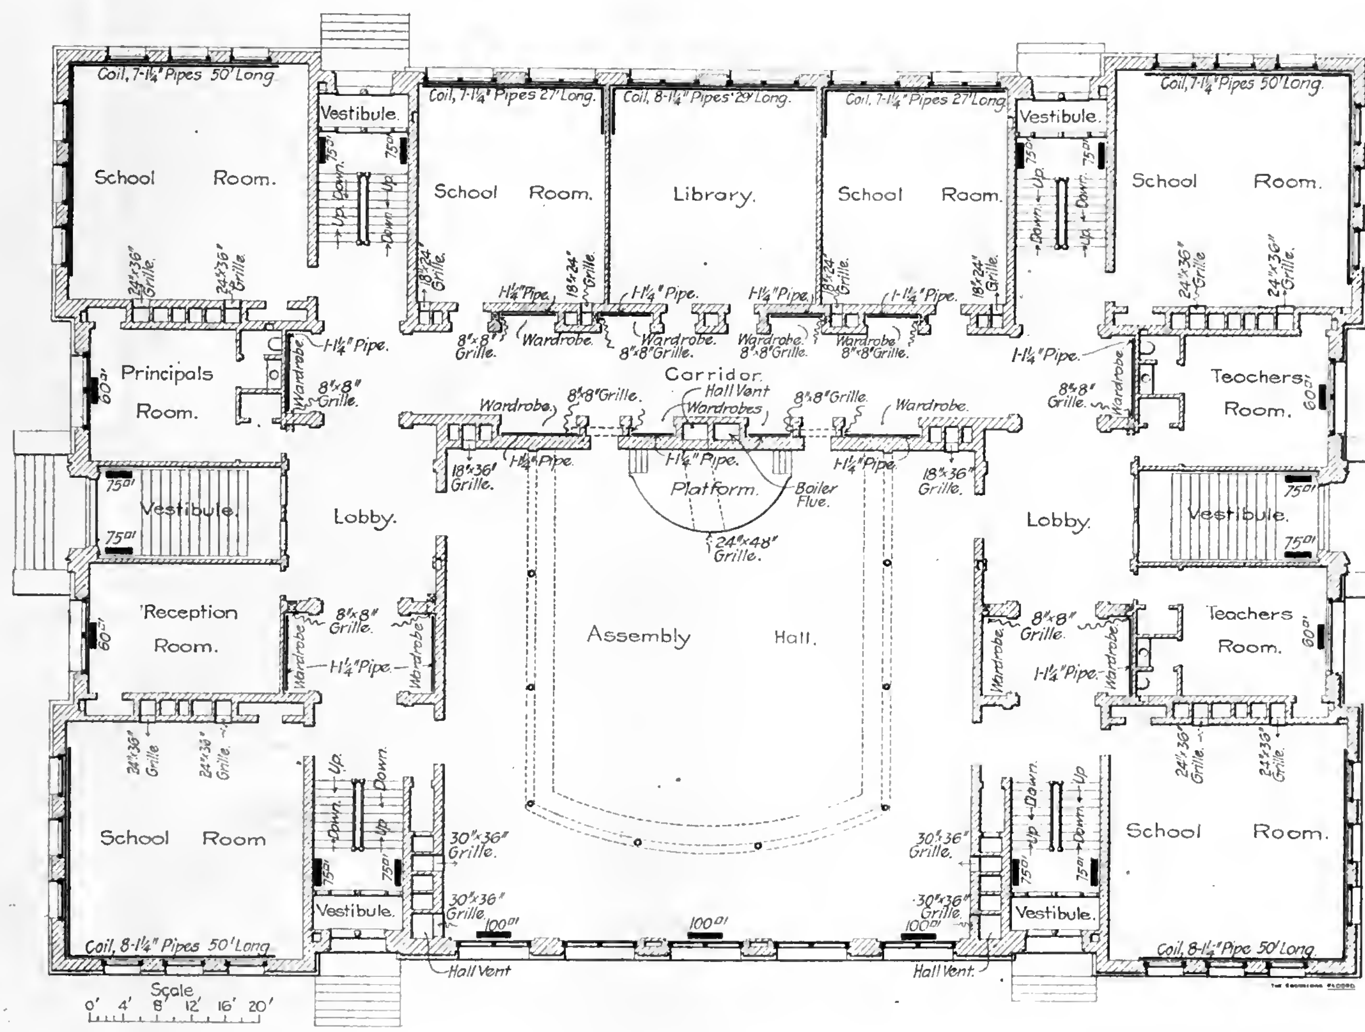
The escape of air from the rooms is accomplished in the usual way through vent openings likewise protected with grilles, the vitiated air rising to the attic space, where ducts convey the air to a central chamber. From this it is removed by means of a disk fan discharging into the atmosphere. In connection with the ventilating system, care has also been taken to provide for ventilation in the wardrobes. An outflow of air is arranged for through galvanized-iron vent flues 8 inches square running to the attic and connected into the system of vent ducts described. These rooms, as explained, are distributed along the corridors and the air passing from them comes from the corridors. Besides thus providing ventilation, the corridors which are furnished with no direct radiation, are warmed somewhat by radiation which has been installed in the wardrobes in the form of a short run of pipe, for the purpose of heating the wardrobes and drying the clothes. The corridors are, of course, comparatively unexposed and on the first floor are warmed by the intermittent inrushes of hot air from the vestibules when doors are opened. The attic fan is an American Blower disk fan 84 inches in diameter driven at 200 revolutions per minute by belt from a 7½-horse-power Eddy motor. The motor is arranged to be controlled by means of a rheostat in the boiler room.

The main toilet rooms in the basement are ventilated independently of the rest of the building. The air rises from each in a flue to the attic, where it is collected, as indicated on the attic plan, at a 30-inch Emerson ventilator and discharged into the atmosphere. For accelerating the air flow through this system, a steam radiator, fed with live steam, of the circular vertical-tube pattern, and having 100 superficial feet of surface, is located below the ventilator. When the heating apparatus is not in use the acceleration of the air flow is accomplished by small cast-iron stoves placed at the base of each flue in the basement.

The Evans exhaust hot-water system was the method adopted for warming, the principal apparatus, as stated, being in the center of the basement. The steam boiler is of the horizontal tubular type with an overhanging front. It was built by Stewart Boiler Works, of Worcester, and consists of a shell 18 feet 4 inches long and 66 inches in diameter and 80 tubes 3 inches in diameter and 17 feet long. It is provided with the Sydney Smith feed heating system. Steam, which ordinarily is generated at 80 pounds per square inch, is carried from the front outlet to the engine of the circulating pump, the blower engine and to the aspirating surface for the toilet ventilation, and from the rear outlet, to which is connected the safety valve, to the auxiliary or live-steam heater belonging to the hot-water heating apparatus. The exhaust of the engines is led to the exhaust heater, which is of the vertical closed steam tube type, and the condensation is piped to the blow-off tank. As usual, the exhaust may by-pass the heater and reach the atmosphere through the usual exhaust riser, which, however, has no back-pressure valve. The auxiliary heater is suspended horizontally from the basement ceiling, so that the condensation can be returned directly to the boiler, and it is of the water-tube pattern. The heaters are designed as feed-water heaters are, account being taken of the small range of temperature through which the water is heated. The circulating pump is a 4-inch Lawrence centrifugal pump, and ordinarily is operated at 400 revolutions per minute from a directly connected vertical Lawrence engine. The pump maintains a difference of pressure of 8 to 10 pounds per square inch between the return and flow connections to it, to overcome friction resistance in circulating. A 5-horse-power 500-volt electric motor has been installed as a relay to the Lawrence engine and for use also at night, when the fires are banked. By this means the heat of the steam generated by the low fire may be distributed throughout the building to the direct radiation surface, preventing much of a drop in room temperature and at the same time doing away with the necessity of a night man.

The method of distributing the water is quite interesting. From the pump the water is forced in turn through the two heaters, both of which are provided with by-passes. The main starts 5 inches in diameter. First the tempering stacks are supplied with a 3-inch branch and the main is then subdivided, as indicated in the basement plan, into four 3-inch loops, each supplying the heating apparatus in one-quarter of the building. The various radiators and coils are all provided, of course, with flow and return connections, but the separate circuits are shunts upon the 3-inch main. The main thus acts as both flow and return, and the four loops are all joined at the centrifugal pump, where the water is again forced through the system. The coils in the rooms of the second and third floors are supplied from the same pair of risers, while those in the first story are connected to independent risers. Similarly the basement coils are independently connected to the main. The ratio of cubic contents to direct radiation surface varies from 60 to 1 to 90 to 1.

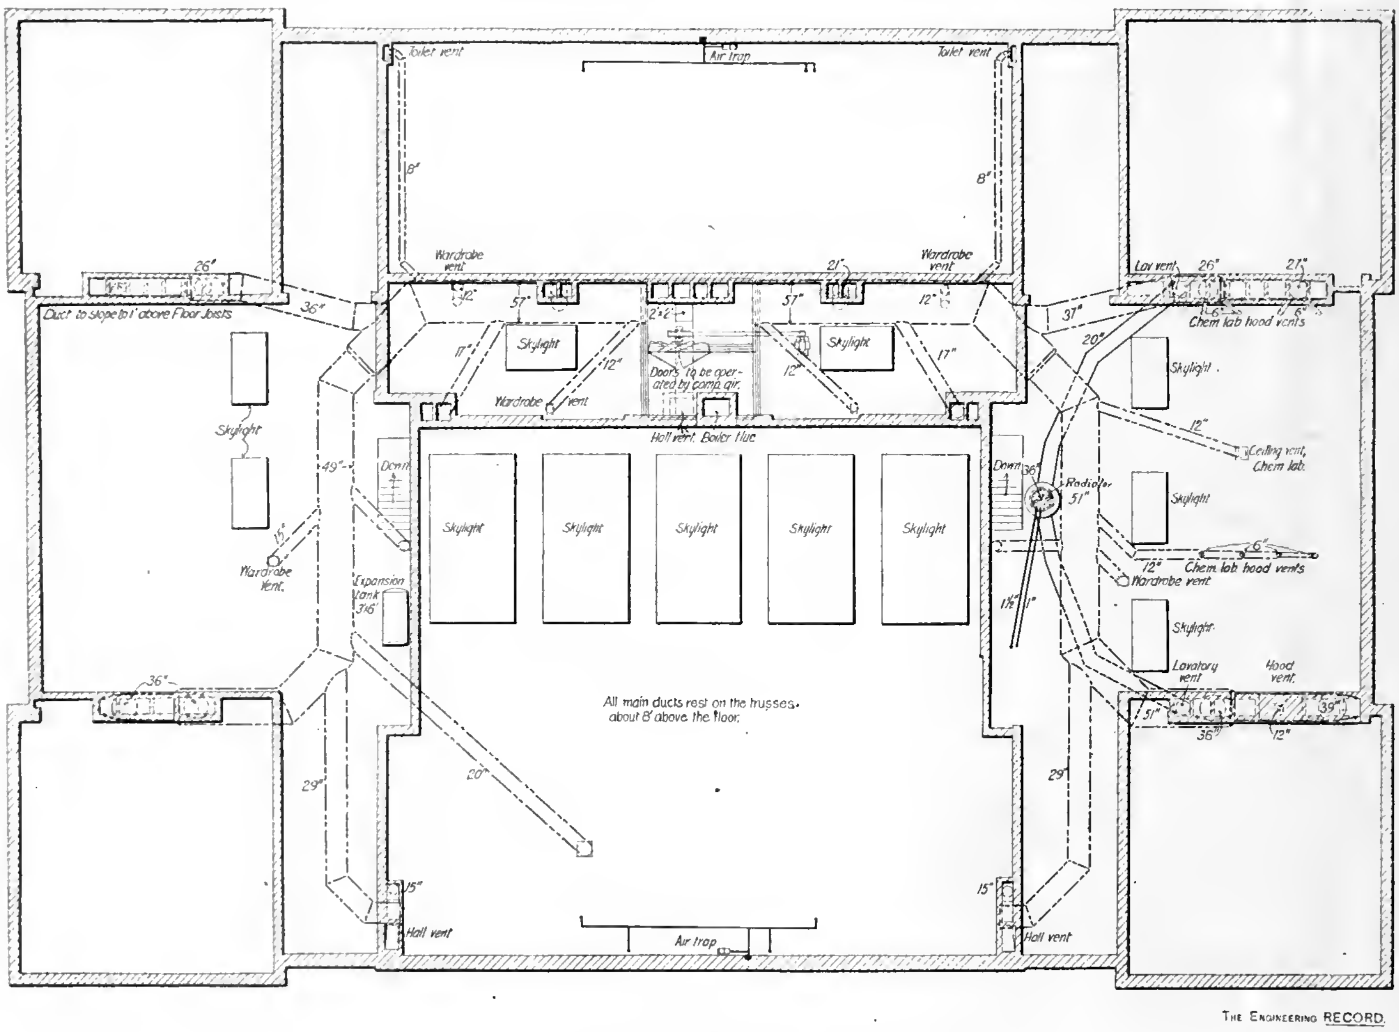
The expansion tank is located in the attic, built of 5/16-inch steel, and is fitted with a 2-



PLAN OF THE FIRST FLOOR.

inch, nickel-seated, pop, safety valve, set to blow at 15 pounds pressure and discharging by a pipe to the blow-off tank in the boiler room. A water-pipe connection is made to the tank and a Kieley automatic boiler feed furnished to maintain a water level near the center of the tank. At two high points in the system, shown in the attic plan, are placed two float traps inverted and used as automatic air vents. The Johnson system of temperature regulation has been installed, with the diaphragm valves controlling the flow of water through the direct radiation coils.

The architects for the building were Messrs. Frost, Briggs & Chamberlain, of Worcester. The heating and ventilating apparatus was designed by Messrs. Evans, Almirall & Company, of New York, patentees of the system of hot-water heating installed. The contractors for the work were O. S. Kendall & Son, of Worcester. The plant cost about $18,000. During the first winter's heating 200 tons of anthracite coal were consumed and two janitors sufficed for all work.



PLAN OF THE ATTIC.

Two English Portland Cement Works.

The general interest in concrete construction which is now evinced abroad is reflected in the numerous articles in the foreign technical press on the manufacture and uses of Portland cement. Among these recent articles were two relating to English cement works, from which a few notes are given below. The first article was a description of the Greenhithe plant of I. C. Johnson & Company, described in "The Engineer."

The works are located over a bed of chalk and close to the River Thames, which affords ample shipping facilities. On a portion of the site the chalk is overlaid by a rich bed of excellent gravel held in sand and loam. This would have in any case to be removed somehow in order to get at the chalk. As a fact, it is being quarried hydraulically by a subsidiary company, which pays a royalty for the privilege, the process having the advantage, besides removing the material, of separating it from the sand and loam. The washing water is led over depositing beds, where the loam falls down in a slurry. This, when mixed with a certain amount of waste from the chalk pits, was found to be an excellent material for making bricks. A brick factory was therefore added, and bricks are manufactured on the site, kilns for this purpose having been erected. The sand, gravel, and larger stones find a ready market. The chalk is brought from the workings on narrow gauge cars and dumped near the wash mills, and the clay is brought to the same place by similar cars running from the wharf where the barges which bring it from the Medway are unloaded.

The clay is kept uniform in quantity at these works and the variation in the proportions of the raw materials is made by changing the amount of chalk. The materials are loaded separately into handbarrows, wheeled over scales where they are weighed, and then dumped into the wash mills which mix them with water into a slurry. The foreman in charge of the weighing is also in charge of the wash mills and is in close communication with the laboratories, which designate at frequent intervals the proper proportions of the ingredients. These variations are stated to be only one pound in 500 pounds in some cases.

The wash mills employed are of the ordinary type, having revolving spider arms carrying depending stirrers. The mingled slurry finds its way through gratings into catch-pits placed at that side of the wash mills remote from the holes into which the clay and chalk are charged. From these pits the mixture is in each case lifted by means of a revolving bucket wheel, which takes it to such a height that it can flow down wooden shoots leading to horizontal stone mills. There are in all six mills driven by bevel gearing from the shaft running under the floor of the building, which is raised off the ground. This shaft also drives the pump, which forces the ground slurry as it comes from the mills through flanged pipes to every part of the works where it is required. The engine for driving these grinders and pump is a horizontal compound condensing engine driving through gearing on a horizontal shaft. It obtains its steam at 80 pounds pressure from a battery of elephant type boilers. This engine runs condensing—as, indeed, do the other main engines in the works. The water necessary for this is obtained a few feet below the surface.

These works, it is said, witnessed the birth of the Johnson chamber kiln, and there are no less than 54 kilns of this kind, but of different types, in various parts of the works. Some of these are of the ordinary tank form, in which the gases go direct over the top of the slurry, when it is being dried, to the chimney. In the later designs the slurry is held on a floor of iron plates carried on brick arches. In these the heated gases generated by the combustion of the charge are first led over the top of the slurry to the end remote from the kiln as in the original form; they then descend by two vertical flues to two horizontal flues running under the iron plates towards the kilns again, these flues being connected to a further horizontal flue running also under the iron plates back to the far end of the chamber and thence to the chimney. Then there are kilns with firing pits, and others—the latest—where these pits are done away with, the fire being carried on removable girders.

Taking them on the average, each kiln will produce 27 tons of clinker per "burn," and three "burns" are obtained from each kiln every 14 days. The tanks are, of course, filled with slurry from the flange pipe already mentioned.

When the burning is finished and the charge has cooled, the clinker, after being carefully inspected and the underburnt portions removed, is taken in trolleys running on narrow-gauge lines to either one of two grinding mills. The first of these consists of three horizontal stone mills in conjunction with a tube mill. The clinker is first broken in a crusher, and is then elevated by means of a bucket conveyor to the stone mills, the delivery from which descends to a tube mill, which in its turn delivers on to an endless belt. This belt drops the cement into a conveyor which communicates with the various bins in the cement warehouse. The engine driving these mills and their accessories is a horizontal cross-compound condensing engine of about 300 horse-power. It obtains its steam from the elephant type boilers already alluded to.

The second and more modern grinding mill has ball mills in place of stone mills, though the finishing is done, as in the first instance, by means of tube mills. Rope-driving is employed throughout—in fact, rope-driving is largely used in all parts of these works—and any one of the mills can be stopped or started at will, irrespective of the others. For taking the cement in its various stages of manufacture about from place to place, either trough conveyors with worms or endless belts are used. Practically speaking, the cement is never touched by hand from the clinker stage until it is delivered, finished, in the storehouses. Here the delivery could be made, were it necessary to do it, direct into sacks or casks for despatch, the length of time it is on the belt serving practically to bring the temperature of the recently-ground cement down to that of the atmosphere. If it is necessary to take the material to a higher level this is done by means of encased bucket conveyors. Here there is a complete dust-collecting plant, the dust being drawn into ducts placed in various positions, and all delivering into a settling room, where the dust collects and falls down shoots to a traveling belt at the lower level. The 225-horse-power engine driving this part of the works obtains its steam from Lancashire boilers. The total storage available on the premises amounts to some 10,000 tons. The weekly output of the works is about 1,300 tons on the average.

The second of the English works to be described is the plant of Martin, Earle & Company, on the Medway near Strood. There are really two plants, the first established in 1894 and the other unfinished at the time of the publication in "Feilden's Magazine" of the notes from which the following account has been condensed. The materials used are chalk obtained just back of the works and clay from marsh land in the vicinity.

The old plant is not unlike others of the same period. The materials are mixed into a slurry in wash mills, ground in wet mills and then run into basins from which pumps supply the 95 Johnson kilns. The clinker is then ground and passed in a finished state to the warehouse, holding 10,000 tons. All stages of the process are supervised by a central laboratory. These works turn out from 2,500 to 3,000 barrels a week.

The new works are noteworthy for the extensive use of American methods of production, and are about equal to the old plant in capacity. The raw materials are mixed in wet mills, but the slurry is passed through a new type of mill before it is pumped to the kilns. The latter are of the rotary type but contain a number of modifications of the pattern usual in the United States. The final form was not adopted until two years of practical working with a full-size kiln had demonstrated its value. Sixteen of the kilns, each 90 feet long and 6 feet in diameter are to be used. They are all driven by worm gearing from a single shaft actuated by a pair of 350-horse-power engines, built in the shops of the company.

The kilns use powdered coal which is dried by the heat of the kilns themselves. It is placed in one end of an annular chamber about the cylindrical shell of the kiln, the revolution of the latter gradually moving the fuel along to the other end, where it is discharged upon conveying apparatus running to the coal mill.

The clinker from the kiln drops into a conveyor which takes it to an elevator running to the top of a cooling tower. Here it passes downward slowly and is cooled by blasts of air forced into the tower at different elevations by a blowing engine. When cooled it is taken by conveyors to a grinding house containing thirty Griffen mills, each mill provided with a chute that discharges directly into the storehouse alongside. This storehouse has a capacity of 10,000 tons.

Personal Notes.

Mr. Ralph H. Sparks has been elected city engineer of Terre Haute, Ind.

Mr. A. O. Cunningham has been appointed bridge engineer of the Wabash Railroad, with headquarters in St. Louis.

Mr. Fred Pardee has been elected constructing engineer of the water and electric light plant to be installed at Hazlehurst, Miss.

Mr. Rudolph Hering has been retained as engineer of the Passaic Valley Sewerage & Drainage Board, which was recently organized to build a joint sewerage system for the cities of that New Jersey district.

Mr. George H. Fenkell has resigned his position as chief draftsman in the engineering department of the Detroit Water Commission to become the civil engineer of the Erie, Pa., Water Commission, which proposes to make extensive improvements of the works under its charge.

Mr. Alonzo C. Hoover has been elected superintendent of the Lebanon, Ind., water-works.

The ownership of the Carthage, Mo., Water-Works Company has changed hands, and Messrs. George G. Bayne and J. M. H. Young, both of Joplin, have been elected president and secretary respectively.

Mr. Epes Randolph, general manager of the Los Angeles Railway Co., has been elected president and general manager of the Cananea, Yaqui & Pacific Railway Co., which is to build a line through Arizona, New Mexico, Colorado and south along the Gulf of California through Sonora and Sinaloa, Mex.

The Tunnel of the Niagara Falls Power Company was inspected on June 1 after five years' use. No brick was out of place and the work seemed as sound as when first put in use. The brickwork was laid in Giant Portland cement mortar.

Civil Engineers are Wanted in the Bureau of Yards and Docks of the Navy Department, and candidates will be examined at Chicago and New York on September 29. No person will be appointed under 27 or over 35 years of age nor one without satisfactory physique, a diploma from an engineering school of repute, five years' practical experience in civil engineering and three years' responsible charge of work. The character of the examination was fully explained in The Engineering Record of February 16 and 23, 1901.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xvi, xviii and xxvii.

WATER.

Roslyn, N. Y.—The contract for furnishing a water supply for fire purposes to Great Neck Water Supply Dist. (bids opened Aug. 18), has been awarded to McFarland & Pierson, 1123 Bway., New York City, at $30 per year each for 40 fire hydrants (5-year contract).

Hartwell, Ga.—J. W. Barnett and O. H. Sheffield, of Athens, Ga., have received the contract for the preparation of plans and specifications for a water works and electric light plant.

Springfield, O.—Bids are wanted Sept. 16 for the purchase of $30,000 bonds issued to provide for the extension of water mains and pipe lines, and for enlarging and improving the water works system. R. N. Lantz, City Clk.

Caldwell, Idaho.—Bids are wanted by the Bd. of Directors of the Pioneer Irrigation Dist. until Sept. 15 for the purchase of bonds to the amount of $197,500. Irwin Bissitt, Pres.

Navajo Agency, New Mex.—See "Government Work."

Middleport, N. Y.—Gen. Mgr. Wallace C. Johnson writes that the Middleport Lighting Co. has an electric light plant now constructed in Middleport and is considering the installation of a water works plant, but no definite steps have as yet been taken.

Cleveland, O.—Bids are wanted Sept. 15 for the purchase of $5,000 sewer bonds maturing Apr. 1, 1914, and $60,000 sewer bonds maturing Oct. 1, 1912; $100,000 water works bonds; $100,000 elevated roadway bonds; $30,000 Walworth Run bridge bonds, and $100,000 market house bonds. H. D. Coffinberry, City Treas.

Minneapolis, Minn.—Bids are wanted by the Com. on Ways & Means Sept. 5 for the purchase of $250,000 municipal bonds. Joshua Rogers, City Compt.

Jamestown, O.—Corp. Clk. Chas. A. Davis writes that the question of constructing water works is under consideration.

Johnstown, Pa.—John Birkinbine, Engr., Odd Fellows' Temple, Philadelphia, writes that the Manufacturers Water Co. is merely investigating possible sites for a dam in Quemahoning Valley; nothing definite has as yet been done.

Mt. Sterling, Ill.—Bids are wanted Sept. 1 for $10,000 bonds issued for the purchase of the present water works; bids are also wanted at the same time for furnishing an elevated water tower and for approximately 2,150 ft. of 6-in., 1,900 ft. 4-in. and 200 ft. of 8-in. standard weight pipe. Engrs., Sturtevant & Todd, Fisher Bldg., Chicago, Ill. J. F. Smith, City Clk.

Roundlake, Minn.—Village Recorder J. C. Thomsen writes that the contract for constructing a system of water works, bids opened Aug. 6, has been awarded to the Des Moines Bridge & Iron Wks., Des Moines, Ia., for $5,440.

Victor, Colo.—City Engr. J. S. Babcock writes that the contract for constructing the Bison Park storage dam, approximately 40,000 cu. yds., has been awarded to Dunphy & Nelson, of Victor, for $23,000.

Grand Rapids, Minn.—Recorder Fred A. King writes that the contract for constructing a water works pumping station has been awarded to Alexander Roberts, Duluth, Minn., for $4,890.

Meadville, Pa.—City Engr. W. A. Doane writes that the city has purchased a site 1¼ miles west of the present water works pumping station (where successful tests were made last year for pure water), and will place the new 4,000,000-gal. pumps there when received.

Galveston, Tex.—City Engr. C. G. Wells writes that it is proposed to lay a water main across the bay; size, 16 in., 24-in. or 30-in.

Kenmore, N. Y.—Busch Bros., Engrs., Mooney Bldg., Buffalo, write that the lowest bids opened Aug. 15 for a water distributing system for Kenmore were as follows: For furnishing pipe, U. S. Cast Iron Pipe & Fdy. Co., at $9,966; for furnishing valves, etc., Darling Pump Mfg. Co., Williamsport, Pa., at $1,700; for pipe laying, L. J. Richardson & Co., Owego, N. Y., at $5,309.

St. Francisville, La.—Bonds to the amount of $10,000 have been issued for water works and an electric light plant.

Brockton, Mass.—City Engr. Chas. R. Felton writes that bids will soon be wanted for a 6,000,000-gal high duty pump.

Ft. Scott, Kan.—This city proposes to require the Water Co. to install filters.

Seguin, Tex.—Dudley D. Baker is Engr. in charge of construction of proposed irrigation plant, estimated to cost $6,000.

Blackduck, Minn.—The Council proposes to put in a water tower and tank.

Dickinson, N. D.—L. A. Simpson and others have asked for a franchise for a water works system.

Wonewoc, Wis.—Village Clk. John Reidy writes that W. G. Kirchoffer, of Baraboo, is Engr. in charge of proposed water works. Estimated cost, $10,000.

Moorefield, W. Va.—The Council is said to be about to offer for sale $6,000 water supply bonds.

Sumas, Wash.—Press reports state surveys are now being made for a system of water works.

Shelbina, Mo.—The matter of establishing water work is under consideration.

Sandwich, Ill.—It is stated that this city will expend $9,000 in repairing and improving the water works and electric light plant.

Ruthven, Ia.—Press reports state that W. H. Lewis will receive bids for the construction of a well 20 ft. in diameter and not over 30 ft. deep.

Madrid, Ia.—The Council is considering a water works system.

Two Harbors, Minn.—T. F. McGillivray, of Duluth, is reported to have been engaged to furnish plans for the new intake pipe, and putting in intake well and constructing a new building for pumping and lighting station.

Peabody, Mass.—Town Clk. Elmer M. Poor writes that Snow & Barbour, of Boston, are the Engrs. in charge of construction of proposed water works. Estimated cost, $150,000.

Hudson, N. Y.—Plans are under consideration for the improvement of the water supply; one plan, which is said to involve an expenditure of about $200,000, provides for a supply from Lake Charlotte.

Oxford, Ind.—The Town Bd. has passed an ordinance providing for the municipal ownership of the water works and electric light plant.

Northampton, Mass.—The City Government has passed an order providing for the issue of $50,000 water bonds.

Bowling Green, O.—Articles of incorporation for the City Water Co., of Bowling Green, have been filed by M. L. Case, F. A. Baldwin, A. W. Rudulph and others.

Dyersville, Io.—The contract for constructing a system of water works, including a 60-ft. steel tower, a pine tank, etc., is stated to have been awarded to G. H. Meridith, of Cedar Rapids, for $6,861.

Mt. Sterling, Ill.—The Council is reported to have ordered the expenditure of $10,000 in improving the water supply.

Girard, Kan.—The Com. on Water Wks. has recommended the purchase at once of a 60-H.-P. boiler, and that the city adopt the meter system of supplying water.

Saticoy, Cal.—The Saticoy Development Co. has filed articles of incorporation, with a capital of $25,000, for the purpose of constructing reservoirs, dams, ditches, pipe lines, pump stations, to furnish and distribute water for irrigation. Directors: David Darling, Chas. N. Kimball, Geo. W. Good, and others, of Saticoy.

Paterson, N. J.—Bids are wanted Sept. 10 by the Jersey City Water Supply Co. for building a reservoir dike at Parsippany, N. J., as advertised in The Engineering Record.

Lansing, Ia.—This city wishes the services of a competent engineer to make plans and specifications for a water works reservoir, as advertised in The Engineering Record.

Athol, Mass.—Local press reports state that the Athol Water Co. proposes to build a dam 30 ft. high to secure a new and additional water supply from Buckman Brook. Estimated cost of new system, $40,000.

Martinsburg, W. Va.—W. S. P. Shields and Geo. A. Rumsey, Jr., of Philadelphia, have submitted a proposition to the City Council Water Bd. to buy, improve and operate the water works in Martinsburg and to install a sewerage system, for which they offer to assume the entire present bonded indebtedness of the corporation of Martinsburg, amounting to $75,000.

Duluth, Minn.—The City Council has passed an ordinance declaring for the purchase of the West Duluth Water & Light Co.'s plants.

New York, N. Y.—Bids are wanted Sept. 4 for furnishing and laying water mains in numerous streets. Robt. Grier Monroe, Comr. Water Supply, Gas & Electricity.

Lorain, O.—It is stated that bids are wanted Sept. 15 for $32,000 water works improvement bonds. J. J. Mahoney, City Clerk.

Ellendale, Minn.—Bids are wanted Aug. 29 for $6,000 water works bonds. E. M. Thompson, Village Recorder.

Burlington, Ia.—The Citizens' Water Co., of Burlington, has filed articles of incorporation. Incorporators: Jas. A. Guest, Seymour H. Jones, W. W. Baldwin, and others, of Burlington. Object, to acquire and operate, improve and extend the existing system of water works in this city, by the consent of the city and under contract with the city. Capital stock, $330,000.

Sacramento, Cal.—Russell L. Dunn, of San Francisco, has made a proposition to the Bd. of Trus. to furnish Sacramento with clear water supply of 11,000,000 gal. daily from the North Fork of American River near Towles, Placer Co.

Salt Lake City, Utah.—The City Council has adopted a resolution providing that a committee, associated with the Mayor, the City Engr. and the Water Comr., consider the feasibility of constructing storage reservoirs to hold flood water in City Creek, Emigration and Parley's canyons.

Scottdale, Pa.—A charter has been granted to the Menallen Water Co., of Scottdale; capital, $1,000. Directors: Chas. E. Loucks, I. D. Evans, Scottdale; S. F. Potter, Greensburg, and others.

Greensburg, Pa.—A charter has been granted to the Donohue Water Co., of Greensburg; capital, $1,000. Directors: John P. and Edw. E. Donohue, Greensburg; B. F. Overholt, Scottdale, and others.

Hebron, Ill.—Press reports state that steps are being taken towards securing a water supply. It is proposed to issue $5,500 bonds to pay for the pumping plant. The $9,300 necessary for water mains to be raised by special assessment.

San Bernardino, Cal.—The City Bd. of Trus. has, according to press reports, decided upon a plan for a city water supply which provides for the purchase of Hubbard water, the building of a reservoir and the laying of new mains, etc.; estimated cost of new plant, $200,000.

Parkersburg, W. Va.—The City Council has appointed a committee to investigate the proposition to secure a pure water supply from wells.

Elma, Wash.—The City Council has decided to employ an engineer to survey McDonald Creek as a proposed source of a gravity water supply.

Barre, Vt.—The City Council has sold bonds to the amount of $60,000 for the purpose of completing the Orange Brook extension of the water works.

Cohoes, N. Y.—The matter of securing a better water supply is under consideration.

Findlay, O.—Engr. McKibben, who has charge of the new water works construction, has made a preliminary report to the Water Wks. Bd. and Council Com. in which he places the estimated cost of the 20-in. cast iron pipe line, with reservoirs, etc., complete, at $217,685.

Barboursville, Ky.—A plan is said to be on foot for the construction of water works.

Bethlehem, Pa.—The Keystone Const. & Engineering Co., of Easton, is reported to have entered into a contract with the Bethlehem Consolidated Water Co. for a sand filtration plant, estimated cost $20,000, to be built in accordance with plans and specifications prepared by J. Marshall Young, of Easton.

Seattle, Wash.—Plans are being prepared by the City Engr. for a new water system in Green Lake and vicinity, also an estimate of the probable cost of building a standpipe in Woodland Park and a pumping station to supply water for that section of the city.

Homestead, Pa.—The Council has sold bonds to the amount of $164,000, said bonds to be used to make repairs to the Boro. water works, erect a garbage plant and redeem outstanding debts.

Washington, D. C.—The Commissioners have issued orders that $50,000 be taken from the water fund and used for continuing the extension of the high service system of water distribution; also that the bid of M. J. Drummond & Co., opened Aug. 16, for furnishing 12-in. cast iron water pipe at $30.70 per gross ton is accepted.

Hawkesbury, Ont.—Bids are wanted Sept. 1 for about 750 tons of cast iron water pipe and special castings, 30 fire hydrants and 22 stop valves, according to specifications prepared by Wm. Kennedy, Jr., Montreal, Que. Address D. Doyle, Town Clk.

Elyria, O.—Contracts for the proposed new water works (Lake Erie to be source of supply) are reported to have been awarded as follows: Valves and valve boxes, to Rensselaer Mfg. Co., Troy, N. Y.; hydrants, to Thos. B. Shaw, Chicago; pipe for force main, to U. S. Cast Iron Pipe & Fdy. Co., $31.50 per ton, total $123,609; intake and crib, to Thather & Shirley, Toledo, $12,850; pipe laying, to Baldwin Bros. & Graham, 55 cts. per ft. for force main, $23,530; 3,000,000-gal. pump, to Snow Steam Pump Co., Buffalo, $20,996.

Enfield, N. H.—Engr. in Charge Arthur W. Dudley, of Manchester, N. H., writes that bids were opened by the Water Comrs. on Aug. 12 and contract awarded to Arthur W. Stone, of Hartford, Vt., as follows: Clearing and grubbing 25 acres, $285; excavating dam site, 2,000 cu. yds., 10 cts.; rock excavation, 50 cu. yds., $3; excavation for core wall trench, 200 cu. yds., 50 cts.; rubble masonry, 420 cu. yds., $5; puddle dam core, 8,000 cu. yds., 40 cts.; earth slopes, 5,800 cu. yds., 35 cts.; masonry waste weir, 110 cu. yds., $5; concrete screen chamber, 20 cu. yds., $6.50; slope paving, 1,875 sq. yds., 60 cts.; total, $16,710.

Yonkers, N. Y.—The following bids are stated to have been received by the Bd. of Water Comrs. for furnishing and erecting at the service station a horizontal high duty compound condensing duplex direct-acting pump having a capacity of 8,000,000 gal. in 24 hours: Thos. A. Lewis, $13,300; R. D. Wood & Co., $23,800; Snow Steam Pump Wks., $18,000; M. P. Davidson, $23,200; Barr Pumping Engine Co., $51,000; The d'Auria Pumping Engine Co., $19,550; Henry R. Worthington, $25,800.

Bids were also received as follows for furnishing and delivering 335 lengths of 24-in. pipe at 2,811 lbs. per length of 12 ft.: John Fox & Co., $32.45 per gross ton; Dimmick Pipe Co., $31.75; U. S. Cast Iron Pipe & Fdy. Co., $34.70; Camden Iron Wks., $32.40; Warren Foundry & Machine Co., $31.

The Bd. of Water Comrs. has adopted a resolution instructing the President to recommend a consulting engineer to perfect plans for the increase of the city water supply from Nepperhan River at the tube well station property and filtration by the sand system.

SEWERAGE AND SEWAGE DISPOSAL.

Harrisburg, Pa.—Bids are wanted Sept. 3 for constructing approximately 3 miles of concrete and expanded metal intercepting sewer, and appurtenances, as advertised in The Engineering Record.

Salem, O.—Bids are wanted Sept. 10 for the construction of sewers in E. 5th, Vine and E. 7th Sts. Geo. Holmes, City Clk.

Alliance, O.—Bids are wanted Sept. 10 for constructing sanitary sewers Nos. 19, 21 and 46. Approximate quantities, 5,840 lin. ft. of 8, 10 and 12-in. pipe. Chas. O. Silver, City Clk.

Cleveland, O.—See "Water."

White Plains, N. Y.—Bids are wanted Sept. 1 for constructing a storm water sewer through and along the Davis Brook; also for a sanitary lateral sewer through Winchester St. Peter Paulding, Village Clk.; B. F. Darling, Village Engr.

Hammond, Ind.—Bids are wanted Aug. 26 for constructing a main sewer of 2-rings brick in Atchison Ave., 115th St., Roberts Ave. and Indiana Boulevard, said sewer to have 2 ft. internal diameter for a distance of 991 ft., the remaining 2,966 ft. to have 3 ft. internal diameter; with manholes, catch basins, etc. Peter J. Lyons, City Engr.

Alton, Ill.—Property owners on Ridge, Union, North and Pearl Sts. have petitioned the Bd. of Local Improve. for the construction of a sewer to drain the northern part of the city.

Cudahy, Wis.—The proposition to issue $25,000 bonds for a sewer system is under consideration.

Oshkosh, Wis.—Bids are wanted Sept. 9 for the construction of sewers in 9th, 10th and Ohio Sts. Frank Monahan, Chmn. Bd. of Pub. Wks.

Bridgewater, Mass.—Town Clk. H. L. Crane writes that surveys have been made by Snow & Barbour, of Boston, for a sewerage system, estimated to cost $50,000, which this town has under consideration. No action will be taken before March next.

East Washington, Pa.—The contract for constructing a sewage disposal plant is stated to have been awarded by the Boro. Council to Wm. Pickett & Co., Washington, Pa., for $5,103.

Green Bay, Wis.—An ordinance before the Council provides for the issue of $50,000 bonds for sewer purposes.

Little Rock, Ark.—The Bd. of Pub. Affairs has been petitioned for a general sewer system for Sewer Dist. No. 28.

Pittsburg, Pa.—Bids are wanted Aug. 30 for constructing 15 and 24-in. pipe and 30-in. brick sewers in portions of Brushton Ave. and for constructing 9, 15 and 18-in. pipe sewers in portions of numerous streets and alleys. The total estimated cost of sewer and paving work, for which bids will be opened Aug. 30, is $250,000. J. Guy McCandless, Dir. Dept. Pub. Wks.

Galveston, Tex.—The contract for 4,800 lin. ft. of 36 to 12-in. vitrified sewer pipe for Tremont St. sewer has been awarded to May & Wainwright, of Galveston, for $10,174, f. o. b. Galveston.

Guthrie, Okla. Ter.—City Engr. T. A. White writes that on Aug. 28 contracts will be let for 13,000 ft. of 8-in. lateral sewers and 6,500 ft. 10-in. mains.

Leominster, Mass.—Town Clk. C. A. Joslin writes that a committee has been chosen to investigate the matter of constructing filter beds for the sewerage system, and to report next spring.

Brooklyn, N. Y.—Bids are wanted Aug. 27 for constructing sewers in Ave. G, Flatbush Ave. and numerous other streets in the Boro. of Brooklyn; the engineer's estimate includes 3,260 ft. of 90-in. and 5,660 ft. of 84-in. brick sewer; 6,230 ft. of 66-in. to 36-in. brick sewer; 4,890 ft. of 24-in. to 12-in. stoneware pipe sewer; 94 manholes; 49 receiving basins, 1,800,000 ft. sheeting and bracing; 895,000 ft. foundation planking and pile capping under sewers, etc. Bids are also wanted Aug. 27 (extension of date) for constructing a sewer in Bedford Ave., from Montgomery St. to Flatbush Ave.; the engineer's estimate includes 1,370 ft. 96-in., 695 ft. 84-in. and 2,460 ft. 78-in., 4,460 ft. 60-in. and 810 ft. 48 and 36-in. brick sewer; 510 ft. 18- to 12-in. pipe sewer; 69 manholes; 44 receiving basins; 250,000 ft. foundation piling; 1,200,000 ft. sheeting and bracing, etc. J. Edw. Swanstrom, Pres. Boro. of Brooklyn.

Bridgeport, Conn.—City Surveyor H. G. Scofield writes that the letting of contracts for 1,200 ft. of 40-in. brick sewer has been postponed (bids were to have been opened Aug. 20).

Bloomington, Ill.—See "Paving and Roadmaking."

Northfield, N. H.—A. W. Dudley, Engr., Manchester, writes that the contract for 7,100 ft. of pipe sewers, 5 flush tanks and 10 manholes, has been let to Osgood Bros., of Nashua, at 50 cts. per lin. ft. for 6 and 8-in. pipe, $1.10 for 10-in. 10 to 18-ft. branches, flush tanks $20 to construct only and manholes $16 to construct only.

Aurora, Ill.—An assessment is in preparation for new system of sewers estimated to cost $4,700.

Champaign, Ill.—Bids will be received until Sept. 6 by the Comrs. of Kaskaskia Special Drainage Dist. at the office of Ray & Dobbins, this city, for furnishing f. o. b. cars at Sadorus, 5,280 ft. of 16-in. tile with connections and laying same in Sub-Dist. No. 9, in said Special Drainage Dist. Abram Crist, Chmn.

San Francisco, Cal.—The City Engr. has been instructed to prepare plans and specifications for the construction of 6th St. main and adjacent sewers. Cost about $40,000. Bids for construction will be received when plans are completed.

Ensley, Ala.—The Council is said to be considering the question of issuing $75,000 bonds for constructing a sewer system, for which preliminary surveys have already been made.

Springfield, O.—The Bd. of Pub. Affairs has adopted resolutions declaring its intention to construct sewers in Ludlow Ave., estimated cost $5,105; Clifton St., $3,305; and Washington St., $2,356.

Erie, Pa.—The City Engr. has placed the estimated cost of constructing an intercepting sewer system in Mill Creek Valley, and across the northern portion of the city, at about $85,000.

Martinsburg, W. Va.—See "Water."

St. Louis, Mo.—Bids will be received by the Bd. of Pub. Improv. until Sept. 16 for constructing sewers in Rock Spring Joint Sewer Dist. Work to include 10x12 ft. concrete and brick sewer; 1,020 ft. of 10.5; 310 ft. of 10-ft.; 1,540 ft. of 8-ft., and 1,630 ft. of 7.5 ft. brick sewers, with all necessary appurtenances. Hiram Phillips, Pres.

Delaware, O.—The Council has passed a resolution authorizing the contract with Ulrich & Williams, of Springfield, for a sanitary sewage disposal plant for $12,900.

Jersey City, N. J.—Mayor Fagan has signed the resolution providing for the reconstruction of sewers in Gardner, Monticello, Belmont and Jewett Aves., and relief sewers in Division St., Harrison, and Ocean Ave. and Henderson St. Total amount to be spent, $47,000.

Ligonier, Pa.—The Council has agreed to accept the plan for a sewerage system, as prepared by J. J. Janeway.

Paducah, Ky.—City Engr. L. A. Washington writes that the matter of extending the sewerage system about 3 miles is now before the Council. Probable cost of proposed improvement, $16,000.

Ludwick, Pa.—Boro. Engr. J. J. Neel, of Greensburg, Pa., writes that the contract for constructing 10,500 ft. of 8 to 24-in. pipe sewers, with 20 manholes, has been awarded to Ott Bros., of Pittsburg, for $6,908. The trench to average 7.5 ft. in depth.

Vincennes, Ind.—The estimated cost of constructing St. Clair St. sewer is placed at $9,000 for brick sewer 42 to 48 in. in diameter.

Cincinnati, O.—The Bd. of Pub. Service is reported to have decided in favor of the construction of a complete sewerage system for the southern portion of Price Hill. Estimated cost of improvement, $46,000.

Boone, Ia.—City Engr. Chas. E. Russell writes that it is proposed to build about 7,000 ft. of 8 and 9-in. sewer in Fair Ground addition.

Port Huron, Mich.—The Common Council has taken preliminary steps toward the construction of a sewer, at a cost of $50,000, to drain the Tunnel Section of the city.

Dallas City, Ore.—It is stated that bids are wanted Aug. 30 for constructing the Washington St. sewer system. Earl Sanders, City Recorder.

Progreso, Mex.—The N. Y. "Journal of Commerce" states that the Municipal Congress of Progreso has issued a call for bids and plans for the drainage of the swamp near the city. It also states that Felipe G. Canton, Columbia Bldg., 29 Bway., N. Y. City, may be able to give further information.

Rapid City, S. D.—The Special Com. to whom was referred the matter of sewering the city has reported recommending the establishment of a sewerage district.

Kenosha, Wis.—An ordinance before the City Council provides for the extension of the present sewer system to all portions of the city not now provided for.

Aberdeen, S. D.—City Engr. VanMeter has completed the survey for proposed surface drainage preparatory to paving the business part of the city.

Fond du Lac, Wis.—Residents of the recent flooded districts have petitioned the Council for a $40,000 storm sewer.

Yonkers, N. Y.—The Aldermanic Com. on Pub. Wks. has recommended that plans and specifications be prepared for a sewer in South Broadway.

Irvington, N. J.—Local press reports state that bids will be received by the Town Council until Sept. 16 for constructing a lateral sewer system.

Monmouth, Ill.—Bids are wanted by the Bd. of Local Improv. until Aug. 30 for constructing sewer outlets and a sewage disposal plant, as advertised in The Engineering Record.

Wauwatosa, Wis.—The Joint Com. on Pub. Bldgs. & Almhouse of the Co. Bd., Milwaukee, has appointed a sub-committee to investigate plans for improving the sewerage system at the county institutions in Wauwatosa. Estimated cost of improvement, according to plans submitted, $8,950 for filter bed, or $16,500 for new septic tank.

New Albany, Ind.—The Special Com. having the matter of providing a system of sewers under consideration has recommended that the City Engr. prepare plans and specifications for such improvement.

New Britain, Conn.—According to local press reports the lowest bid received Aug. 18 for Section 1 of the proposed sewage disposal system, which calls for the building of 31 filter beds, requiring the removal of 130,000 cu. yds. of material, and the laying of about 7 miles of underdrains and 1 mile of 24-in. main trunk feed sewer, etc., was from Jas. F. Gaffney, of Waterbury, at $31,250.

Saratoga, N. Y.—Sewer bonds to the amount of $50,000 have been sold by this city.

High Point, N. C.—Local press reports state that a municipal sewerage system is about to be constructed.

Waukegan, Ill.—The estimated cost of constructing the south side sewer has been placed by Engr. Smith at about $30,000.

Dubuque, Ia.—The City Council has under consideration the expenditure of $50,000 for the extension of sewers in the northern part of the city.

Watertown, N. Y.—The Bd. of Pub. Wks. has passed resolutions providing for the construction of sewers in Brainard, Pleasant and several other streets, at a cost of about $9,600.

Washington, D. C.—Bids will be received by the Comrs. D. C. until Sept. 13 for constructing sewers in the District, as advertised in The Engineering Record.

Marblehead, Mass.—F. L. Fuller, of Boston, is making surveys and plans for a system of sewerage for this place.

Burlington, Ia.—City Engr. Emmet Steece writes that the City Council has ordered 9,000 ft. of tile sewers.

Abilene, Kan.—Burns & McDonnell, Consulting Engrs., Kansas City, Mo., write that the contract for 24,654 ft. of 6 to 15-in. pipe sewers, 54 manholes, 4 lampholes and 18 flush tanks, has been awarded to Rackliffe & Gibson, of St. Joseph, Mo., for $14,592. The trench to average 9 ft. in depth and be excavated in earth.

Indianapolis, Ind.—The Bd. of Pub. Wks. has, according to local press reports, awarded the contract for constructing the Northwestern Ave. sewer to W. K. Cooper, at $6.42 per lin. ft.; total length of sewer 10,825 ft. This sewer in 24th St. is to be semi-circular 10 ft. in diameter, and in Northwest Ave. for a distance of 1,400 ft. it is to be constructed of concrete and steel, 12½ ft. wide and 3 ft. deep. Street cars will run over this portion. Nearly the entire sewer outside of the concrete section is to be of brick. Engineer's estimate of the cost, $74,750.

Vicksburg, Miss.—The following bids were opened Aug. 14 for grading and drainage of Sections 2 and 3 (6 miles) of Confederate Ave., in Vicksburg National Military Park; the work includes 33 pipe culverts, with masonry head walls, and 75,200 cu. yds. of excavation: Israel Bobbitt, $23,050, 8 months; Nicholson & Williamson (awarded), $20,545, 7 months; H. B. Garbish, $21,200, 8 months; Helgason Bros., $25,012, 8 months; A. L. Dalton, $22,835, 6 months.

BRIDGES.

St. Paul, Minn.—The property owners have petitioned the Aldermanic Com. on Streets to construct a bridge, 40 ft. wide, at Arcade St. Probable cost, $66,000.

Brooklyn, N. Y.—Press reports state that Barth S. Crowin has secured the contract to construct a bridge at U Ave. for $15,800.

The Brooklyn Rapid Transit Co. has been granted permission to construct an iron bridge at Lincoln Road.

Arcola, Pa.—Press reports state that the Perkiomen R. R. Co., controlled by the Philadelphia & Reading R. R., has awarded to the Phoenix Bridge Co., of Philadelphia, the contract to build an iron girder bridge in this city, which will replace present wooden structure. The bridge is to be 65 ft. long, and will cost, according to reports, about $5,000.

Vicksburg, Miss.—Contracts for bridge to be located on Confederate Ave., Vicksburg National Military Park, have been awarded as follows: Glass Bayou bridge to the Penn Bridge Co., Beaver Falls, for $17,500; A. & V. R. R. bridge, to American Bridge Co., for $5,740; Stouts Bayou bridge, to Geo. H. Crafts, Atlanta, Ga., for $23,319.

Alexandria, S. D.—Bids are wanted Sept. 2 for 2 steel bridges in Hanson Co. H. P. Benjamin, Co. Aud.

Portsmouth, O.—Fred. Thompson, Engr. in Charge, Dept. of Yards & Docks, Navy Yard, has completed plans for a $5,000 concrete and steel bridge, which is to be constructed across Guthrie Creek, from the city to the Naval Hospital.

Ligonier, Pa.—It is stated that the building of an iron bridge across Mill Creek, about 2 miles west of Ligonier, is contemplated.

Wilkesbarre, Pa.—Local press reports state that Co. Comrs. will readvertise for bids for constructing 14 stone bridges in different parts of the county, no bids for rebuilding these bridges being received on the last advertisement.

Trenton, N. J.—The Bd. of Freeholders is considering the replacing of Olden Ave. bridge, recently damaged by freshets, with an entire new structure.

Pittsburg, Pa.—Recorder Brown is said to advocate the building of a bridge across the gully, connecting Craft Ave. with Franklin St.

San Diego, Cal.—Plans are being prepared for a wooden, a combination wood and steel bridge and a steel bridge, to be built across San Diego River, on Poway Road.

Milwaukee, Wis.—The Finance Com. of the City Council has recommended the passage of an ordinance for the issue of $100,000 bonds, with which to build a bridge at W. Water St.

Mason City, Ia.—The City Council has adopted an ordinance approving viaduct plans submitted by the Engr. of the Iowa Central Ry. and has granted authority to said Railway Co. to construct a viaduct at State St., according to said plans.

Pottstown, Pa.—The Co. Comrs. have plans for a stone bridge to be built in East Coventry Township.

Bath, N. Y.—Bridges in this county are stated to have been damaged by freshets to the amount of $30,000, and the Co. Superv. are contemplating the issue of bonds with which to replace several.

O'Fallon, Ill.—The building of an iron or steel bridge in this town is being considered.

Philadelphia, Pa.—Ch. Brooks of the Bureau of Highways, in his report to the Dir. of Pub. Wks., estimates that $37,000 will be needed to repair about 14 structures in this city, which require immediate attention.

Local press reports state that plans have been approved by the Bd. of Superv. for 3 piers and western abutment of the proposed Passyunk Bridge, for which $50,000 is available, and bids will soon be asked. The total cost of the structure will be about $1,000,000.

Valley, Neb.—The Commercial Club has petitioned the Co. Comrs. to construct a bridge across Platte River, in Valley, and have offered to contribute $5,000 toward the construction provided a $15,000 structure is built.

Flandreau, S. D.—Bids will be received by the Co. Comrs. until Sept. 2 for constructing an 80-ft. steel bridge across Big Sioux River. A. J. Vallier, Co. Aud.

Louisville, Ky.—The Special Com. of the Bd. of Trade has recommended that viaducts or tunnels be constructed at 9th, 7th and 14th Sts., according to plans prepared by the City Engr., said viaducts to be not less than 14 ft. in the clear and to be large enough to permit the passage of street cars.

Reading, Pa.—Engr. M. M. Dreibelbis has prepared plans for 2 bridges, which are to be built in Berks Co. very shortly. One, an 80-ft. steel single span structure, is to be built across the West Branch of Perkiomen River, in Washington Township; the other, a 60-ft. structure, also across Perkiomen River in Hereford.

Wellsburg, W. Va.—Press reports state that the Wellsburg-Brilliant Bridge & Ferry Co. has been chartered to construct and operate a toll bridge and to operate a ferry across Ohio River, between Wellsburg and Brilliant. Capital stock, $50,000.

Colfax, Wash.—Local press reports state that bids will be received by the Co. Comrs. in Sept. for the building of a steel girder bridge on the South Palouse, and that bids for building the retaining wall, abutments, and other work necessary to reach the bridge will be received by the City Council some time soon.

Perkins, Okla. Ter.—It is stated that the Co. Comrs. at Stillwater have decided to construct a steel bridge across Cimarron River, in this city, and will soon ask bids for constructing same.

Gonzales, Tex.—E. P. Alsbury & Son, of Houston, are stated to have secured the contract to raise and replace the steel bridge across Guadalupe River, in this city, which was damaged by the freshets. The contract price is said to be $5,700.

La Crosse, Wis.—Reports state that the building of a steel bridge, which will replace present pontoon structure across West Channel, is being considered. Probable cost, $7,900.

Mt. Vernon, O.—It is stated that the Cleveland, Akron & Columbus R. R. will replace its trestle in this city with a steel bridge. S. M. Russell, Engr. M. W., Akron.

Camden, N. J.—Press reports state that bridges in this County have been damaged, by the recent freshets, to the amount of $30,000.

Pittsburg, Pa.—The officials of the Pennsylvania R. R. are said to be preparing to make improvements which will eliminate many curves along the main line. These improvements, it is stated, will include the building of 4 bridges in Packsaddle Dist.

Sylvan Beach, N. Y.—See "Electric Railways."

El Paso, Tex.—The street car railway and the railroad companies have made a proposition to the City Council to construct a viaduct at San Francisco St., provided the city will accept said viaduct and keep the same in repair.

Castroville, Tex.—Plans, specifications and estimated cost, for a steel and iron wagon bridge, with 16-ft. roadway for both stone piers and steel piers separately, across Medina River at Castroville, will be received by Medina Co. Commr.'s Court at Hondo, until Oct. 1. H. E. Haass, Co. Judge.

Marshall, Ill.—Bids are wanted Aug. 28 for building a 70-ft. single span, steel bridge across Clear Creek, between Wabash, Ill., and Sugar Creek, Ind. Frank Church, Chmn. Com. of Supervisors, Clark Co., Marshall, Ill.

Cleveland, O.—See "Water."

Mansfield, O.—Bids are wanted Sept. 13 for constructing a steel viaduct, as advertised in The Engineering Record.

Bloomington, Neb.—Plans, specifications and bids will be received by the Co. Clk. until Sept. 9 for constructing a 75-ft. steel bridge at Campbell.

New Brunswick, N. J.—Bids will be received by the Co. Bd. of Chosen Freeholders at New Brunswick until Sept. 3 for furnishing material and constructing a highway bridge to be known as "Amboy Bridge" across Raritan River, from Perth Amboy to Sayreville, near South Amboy. The bridge is to consist of timber deck spans on piles and a steel swing span across the channel of said river. Appropriation, $150,000. Asbury Fountain, Dir.; Thos. H. McCann, Engr. in charge of construction.

Ypsilanti, Mich.—The King Bridge Co., Cleveland, O., is reported to have secured the contract to construct a bridge across Huron River, for $6,600.

Richmond, Va.—The construction of a bridge at 6th St. is being considered.

Boston, Mass.—Bids will be received by Wm. Jackson, City Engr., until Aug. 27 for building 3 piers of Broadway Bridge; $15,000 bond required.

Appleton, Wis.—Bids are wanted Sept. 3 for building a bridge over Fox River, as advertised in The Engineering Record.

Portland, Ore.—Bids will be received by the Co. Comrs. at Portland until Aug. 30 for reconstructing the combination Pratt truss bridge and straining beam bridge over Sandy River, about 16 miles from Portland. F. S. Fields, Co. Clk.

Philadelphia, Pa.—See "Electric Railways."

Three Rivers, Mich.—It is stated that bids are wanted Aug. 30 for constructing a cement arch bridge, 160 ft. long and 60 ft. wide, across St. Joseph River. Jas. E. Bunn, City Clk.

Bluffton, Ind.—See "Electric Railways."

Linneus, Mo.—It is stated that bids are wanted Sept. 1 for constructing 5 steel bridges in this county. T. L. McMichael, Bridge Comr.

Moorhead, Minn.—See "Electric Railways."

Belleville, Ont.—It is stated that bids are wanted Sept. 8 for constructing a steel pin-covered overhead truss highway bridge, having 1 span 95 ft. long and 16 ft. wide. Wm. R. Aylsworth, Co. Clk.

Memphis, Tenn.—Bids will be received by J. H. McBride, Co. Treas., until Sept. 2 for $100,000 bonds. Said bonds are issued for the purpose of constructing bridges and erecting a court house in said county.

South Valley, N. Y.—Bids will be received until Sept. 2 by Chas. A. Boyd, State Supt. of Pub. Wks., Albany, for constructing a bridge across Allegany River, on the Allegany Indian Reservation in South Valley.

Delphi, Ind.—Bids will be received by the Bd. of Co. Comrs. until Sept. 1 for constructing 2 arches, culverts or bridges in Madison Township; 2 arch culverts in Clay Township, and 1 arch culvert in Jefferson Township. Henry Wagoner, Chmn.

Catlettsburg, Ky.—Bids will be received by the Co. Surv. until Sept. 10 for constructing 7 steel or wooden bridges in this county. E. E. Lawrence, Co. Clk.

Fowler, Ind.—Bids will be received by the Co. Comrs. until Sept. 3 for constructing several small steel bridges. Jas. S. Smyth, Co. Aud.

Pittsfield, Mass.—A correspondent writes that the contract for constructing a 133-ft. span bridge at Dalton Ave. has been awarded to the N. E. Structural Co., of Boston, for $12,623.

Providence, R. I.—The following bids were opened Aug. 15 for the steel superstructure of the Merino Bridge over Woonasquatucket River, in line of Egan and Chattiet Sts.: *a*, steelwork complete, 328,000 lbs.; *b*, railing, 338.5 lin. ft.; *c*, totals: Boston Bridge Wks., Boston, Mass., *a* 5½ cts., *b* $3.50, *c* $19,225; Variety Iron Wks. Co., Cleveland, O., *a* 5.9 cts., *b* $4.50, *c* $20,875; New England Structural Co., Boston, *a* 5.8 cts., *b* $3.90, *c* $20,344; J. H. Tower, Providence, *a* 5.69 cts., *b* $4.25, *c* $20,102; Canton Bridge Co., Canton, O., *a* 5.95 cts., *b* $4.10, *c* $20,904. Local press reports state that the contract has been awarded to the Boston Bridge Wks.

PAVING AND ROADMAKING.

Troy, N. Y.—Bids will be received by the Bd. of Contract & Supply until Aug. 20 for regulating and paving with brick on a concrete foundation portions of Washington and 26th Sts. and Second Ave. Jas. M. Riley, Clk. pro tem.

Pittsburg, Pa.—Bids are wanted Aug. 30 for paving with asphalt on portions of numerous streets and for grading, curbing and paving with block stone on portions of 5 streets. J. Guy McCandless, Dir. Dept. of Pub. Wks.

Brooklyn, N. Y.—Bids will be received by J. Edw. Swanstrom, Boro. Pres., until Sept. 3 for regulating and repaving with asphalt on portions of several streets, requiring in all about 15,460 sq. yds. Bids will be received at the same time for regulating, grading and paving with asphalt, about 8,290 sq. yds., on Woodruff and 7th Aves., and for paving with granite on a concrete foundation with tar and gravel joints between tracks and rails of the Brooklyn Rapid Transit Co., on Flatbush Ave., from Malbone St. to Church Ave. Engr.'s estimate, 4,438 sq. yds. of granite and 500 cu. yds. of concrete.

Loda, Ill.—An appropriation of $3,000 has been made for street improvements and $7,000 will be expended in the construction of concrete walks.

Scottdale, Pa.—The Council has passed an ordinance authorizing the grading, curbing and paving with brick of Pittsbrug St. J. P. Owens, Ch. Burgess.

Randolph, N. Y.—The taxpayers have voted to purchase a stone crusher at a cost of $1,300.

Monmouth, Ill.—The Council is said to be preparing to let contracts for 10 blocks of paving.

Ludington, Mich.—The City Engr. has been instructed to prepare estimates of the cost of macadam paving on W. Ludington and S. Washington Aves. and James St.

Topeka, Kan.—The Good Roads Com. recommends that W. 6th St. road be macadamized to a width of 25 ft.

Vincennes, Ind.—Co. Auditor J. D. Williams writes that the contract for constructing about 22 miles of gravel road in Washington Township has been awarded to Cloud, Carr & Monical of Orleans, Ind., for $43,777.

St. Clair, Mich.—Bids will be received Aug. 25 for 30,000 sq. yds. of brick, asphalt block, cedar block or bituminous macadam paving. Willis F. Brown, of Toledo, Consulting Engr.

Bloomington, Ill.—City Engr. E. Folsom writes that a brick pavement and 18-in. pipe sewer will be laid on South East St.

Galveston, Tex.—The contract for furnishing 500,000 vitrified bricks for paving Tremont St., has been awarded to the Tex. & Pacific Coal Co., of Ft. Worth, at $17.60 per M. for "Thurber brick," f. o. b. Galveston.

Boston, Mass.—Bids are wanted Sept. 4 for paving street and building drains and catch basins on the Commonwealth Flats at S. Boston. Woodward Emery, Chmn. Harbor & Land Comrs.

Massillon, O.—Bids are wanted Sept. 10 for furnishing material and labor for the paving of several streets with brick, in all about 17,000 sq. yds. of paving and 4,900 lin. ft. of curb reset. T. H. Seaman, City Clk.

Nashville, Tenn.—A bill before the Council provides for the appropriation of $25,000 to pave Russell St. with bituminous macadam.

Alton, Ill.—It is proposed to pave Bluff St. with vitrified brick.

Seattle, Wash.—Property owners in the 5th Ward have petitioned for asphalt paving in 8 streets; estimated cost about $80,000.

St. Paul, Minn.—The Bd. of Pub. Wks. has under consideration the construction of a macadam road on West 7th, from Tuscarora St., where the sandstone paving will end, to the Ft. Snelling bridge, a distance of 3 miles.

Frederick, Md.—The Bd. of Aldermen has awarded the contract for paving on East Church St., to J. U. Fritchey, of Lancaster, Pa., at his bid of $1.97 per sq yd. for Mack block, and $1.12 per ft. for dressed granite curbing.

Memphis, Tenn.—Local press reports state that Union St. is to be widened and paved with asphalt.

Minneapolis, Minn.—The Council has ordered the following pavements for next year: 8 streets with sandstone, 2 streets with granite and 1 street with brick.

Wheatland, Ia.—Bids are wanted by Com. of the Town Council, until Aug. 28 for macadamizing a portion of Jefferson St.

Hamilton, O.—Bids are wanted Sept. 6 for the improvement of High St. by paving with either sheet or block asphalt, brick or macadam; also grading, curbing, etc. M. O. Burns, City Clk. L. A. Dillion, City Engr.

Windsor Locks, Conn.—Bids are wanted Aug. 26 for the construction of a telford and macadam road in this town. L. C. Seymour, First Selectman.

Duluth, Minn.—The contract for paving a portion of East Superior St. with Trinidad Lake asphalt, has been awarded to the Barber Asphalt Paving Co. for $54,760.

Three Rivers, Mich.—The City Clk. is said to have been directed to engage an engineer to prepare plans for paving Flint Ave.

Marquette, Mich.—Press reports state that the Council has decided to expend $10,000 in improving Lake Shore Boulevard.

Sterling, Ill.—The city is reported to have appropriated $10,000 for macadam streets

Chester, W. Va.—Bids are wanted Sept. 8 for grading, paving and curbing Carolina Ave., 2d St., Virginia Ave. and 1st St., according to plans on file in the office of J. C. Boyd, City Engr., East Liverpool, O. J. S. D. Mercer, Recorder.

Toledo, O.—Bids are wanted Sept. 15 (extension of date) for the improvement of Bancroft and Curtis Sts., with block pavement; bids are also wanted at the same time for block paving on Michigan St. Chas. H. Nauts, City Clk.

Property owners are said to have voted in favor of paving with asphalt block on Cherry St.; the only bid received for this material was from C. H. Burchinal at $46,456 with concrete foundation, or $38,457 with sand foundation.

Crookston, Minn.—City Engr. Geo. A. Ralph writes that the Barber Asphalt Paving Co., St. Paul, submitted the following bid on Aug. 12: asphalt paving per sq. yd., $2.25; granite curb, $1; sandstone curb, 80 cts.; 3-in. tile drain, 8 cts.; total, $47,137.

Decatur, Ill.—City Engr. G. V. Loring writes that the contract for improving Lincoln Sq. and N. Main St. has been awarded to the Green River Co., St. Louis, Mo., as follows: excavation, 25 cts.; gutter flag, 40 cts.; combined curb and gutter, 50 cts.; resurfacing, 89 cts.; asphalt paving on concrete, $1.89.

Richmond, Va.—The Permanent Street Improvement Com. is reported to have decided to ask for an annual appropriation of $300,000 for the next 10 years, for permanent street improvements. W. E. Cutshaw, City Engr.

Evansville, Ind.—The Bd. of Pub. Wks. has adopted resolutions for the improvement, by paving, with asphalt of Walnut, 1st and Mulberry Sts.

Little Rock, Ark.—Local press reports state that bids are about to be received by the Bd. of Pub. Affairs for paving W. Markham St. with asphaltum.

POWER PLANTS, GAS AND ELECTRICITY.

Little Rock, Ark.—An ordinance has been introduced in Council granting permission to W. W. Hippolite to construct a gas plant.

Portsmouth, Va.—The Peoples' Light & Power Co. is reported incorporated to construct an electric light plant. John G. Tilton, Pres.

Coshocton, O.—The Coshocton Light & Htg. Co. is reported incorporated, with a capital of $250,000, to operate a heat, light and power plant in Coshocton. Incorporators: W. A. Hainsbaugh, J. D. Severns and T. L. Montgomery, all of Coshocton.

Galion, O.—The City Council has granted a franchise to the Logan Natural Gas & Fuel Co.

Royalton, Minn.—It is stated that R. E. Lester, of Little Falls, Minn., contemplates establishing an electric light plant at Royalton.

Schoharie Falls, N. Y.—Henry W. Grieme and B. E. Machold, of Amsterdam, are stated to have secured the contract for extensive repairs to the power plant of the Empire State Power Co. at Schoharie Falls for about $60,000. The present dam is to be extended 210 ft., and a dike more than 700 ft. will be constructed. It is reported that next year the company will erect a power plant at Mill Point and a storage reservoir in the Helderbergs.

Plaquemine, La.—The City Council has granted a franchise for an electric light and power plant to Dr. W. A. Holloway, Fred Wilbert, and others, all of Plaquemine.

St. Francisville, La.—See "Water."

Lodi, Cal.—It is reported that Cary Bros. will install an electric light plant for the town.

Eaton, Colo.—The Eaton Light & Power Co. is stated to have secured a franchise to construct an electric light plant. W. W. Petrikin and E. W. Goodwin are reported interested.

Clintonville, Wis.—Langstadt & Meyer, of Superior, are stated to have secured the contract for constructing the municipal electric light plant for $12,000.

Hamburg, N. Y.—The Pierce Light, Heat & Power Co., of Hamburg, has been incorporated; capital, $5,000. Directors: W. G. Venner, Hamburg; D. W. Allen, Buffalo, and H. D. Pierce, of Water Valley.

Dansville, N. Y.—The Village Trus. are stated to have granted a franchise to the Mill Creek Electric Light & Power Co. The Trus. are also reported to have awarded to the company the contract for lighting the village for a term of 5 years from Aug. 1, 1903, for $3,000 per yr.

Rochester, Ind.—The Rochester Electric Light, Heat & Power Co., of Rochester, has been incorporated; capital, $50,000. Directors: J. E. Beyer, C. F. Rosenbaum and F. E. Bryant.

Annville, Pa.—Tobias Bomberger is reported interested in the construction of an electric light plant.

Chicago, Ill.—Bids are wanted by the Bd. of Trus. of the Sanitary Dist. of Chicago until Oct. 15 for constructing certain works for the conservation of the water power on the channel of the Sanitary Dist. of Chicago and the Desplaines River; the work for which bids are asked covers two separate locations: First, in the vicinity of Lockport, the preparation of wall foundations, building of concrete retaining walls, excavation of a channel above and below the site selected for power development, building sluice ways, levees and other works auxiliary to the project of power development. Second, in the vicinity of Hickory Creek, near the southern limits of Joliet, excavation and preparation of foundations for a dam and a tail race, building of concrete masonry dam, together with coffer dams, levees and all auxiliary work necessary to execution of plans for the work. Thos. A. Smyth, Pres. Bd. of Trus.

Oskaloosa, Ia.—The Traction & Light Co. will soon let contracts for the construction of brick buildings for power house, shops and car barn; also for smoke stack 7 ft. in diameter and 125 ft. high. J. H. Springfield, of Ottumwa, is Supt.

Winterset, Ia.—City Clk. H. S. Ely writes that on Aug. 5 it was voted to issue $10,000 bonds for enlarging and repairing the electric light plant, bids for said work to be opened Aug. 25. L. O. Klein, Engr. in Charge.

Winona, Minn.—The City Council has under consideration the advisability of constructing a lighting plant to be run in connection with the present water works. Estimated cost $50,000.

Akron, O.—Bids are wanted Sept. 13 for furnishing material and supplying the city with lights for a period of 5 years. Said bids shall be for furnishing 800 or more vapor street lamps of 16 c. p. each and 1 or more incandescent naphtha lamps of 70 c. p. each, to be lighted on moonlight schedule. Chas. H. Isbell, Clk. City Comrs.

Hartwell, Ga.—See "Water."

Elmira, N. Y.—Bids will be received by Dr. Chas. F. Howard, Pres. Bd. of Mgrs., N. Y. State Reformatory, Elmira, until Sept. 3 for installing engines and generators, switchboard and connections at the Reformatory.

Columbus, O.—Bids will be received by Clarence M. Addison, Clk. Bd. of Pub. Wks., until Sept. 5 for furnishing material and constructing an electric light plant as follows: 3 cross compound condensing engines (vertical or horizontal) of 600 H.-P. each at 150 revolutions; 2 condensers (jet or surface type); 3 400-Kw. steam turbines and generators; 4 horizontal water-tube boilers, 300-H.-P. each, with straight tubes; 1 175x9 ft. self-supporting steel chimney; fuel economizers; 3 500-Kw., 2-phase, 60-cycle alternating current generators, for direct connection to engines; 1,500 7.5 ampere series alternating enclosed arc lamps. Fred J. Immel, Dir. Pub. Improv.

Oxford, Ind.—See "Water."

Baker City, Ore.—The City Council has decided to receive bids Sept. 2 for furnishing and maintaining 40 arc street lamps for a period of 1 year from Nov. 1, 1902.

Sandwich, Ill.—See "Water."

Berlin, Wis.—Geo. Warnking, of Oshkosh, is stated to have secured a franchise for a gas plant.

Bryn Mawr, Pa.—Cope & Stewardson, 320 Walnut St., Philadelphia, are stated to have completed plans for a dormitory for Bryn Mawr College, to cost $130,000. They are also reported to be preparing plans for a library to cost $250,000, and a main heating plant to cost $120,000.

Baltimore, Md.—Crook, Horner & Co., 303 N. Howard St., are stated to have secured the contract for ventilating and heating the school at Johnson and Heath Sts. for $6,300.

North Adams, Mass.—J. McA. Vance, of Pittsfield, is stated to have completed plans for the normal school dormitory. It will be 3 stories high and have a frontage of 156 ft.; the depth of the main building will be 44 ft., and there will be a wing at each end 56 ft. long and 40 ft. wide.

Denton, Tex.—Dennis Mahoney, of Waxahachie, is stated to have secured the contract for erecting the Girls' Industrial School at Denton, for $45,462.

Chicago, Ill.—A. F. Hughes, 437 W. 69th St., is stated to be preparing plans for a 2-story brick parochial school to be erected on 78th St. and Cheltenham Ave., to cost $35,000.

Columbus, O.—The Trus. of the Ohio State Univ. at a meeting Aug. 12 approved plans for the new Veterinary Building to cost $35,000; returned to the architect for revision the plans for the Physics Building, appropriation $130,000, and rejected bids received for the addition to the Chemical Hall, as all were in excess of the appropriation, which is $20,000. New bids will be received for the latter structure.

Marlin, Tex.—The plans of S. P. Herbert, of Waco, are stated to have been accepted for a brick school to cost $22,000.

Youngstown, O.—Bids are wanted Sept. 1 for the purchase of $28,000 school bonds. Edw. R. Thompson, Pres. Bd. of Educ.

Delray, Mich.—Malcomson & Higginbotham, Moffat Bldg., Detroit, are stated to be preparing plans for a school to be erected in the western part of the village, to cost $50,000.

Greeley, Colo.—J. A. Woodbury, of Greeley, is stated to have secured the contract for erecting the west wing of the Greeley High School for $28,991.

Pardeeville, Wis.—Local press reports state that bids will be received by the School Bd. until Sept. 4 for erecting a 6-room school.

Cincinnati, Ia.—It is stated that bids are wanted Sept. 15 for erecting a brick school. J. M. Sturdivant, Pres.

Passaic, N. J.—Swenson Bros., of Passaic, are stated to have secured the contract for erecting the 4th School for $52,000.

San Antonio, Tex.—It is stated that the Oblate Fathers, of this city, will erect on Laurel Heights, north of the city, a theological seminary, to cost about $75,000.

Bloomington, Ind.—Bids will be received until Sept. 3 by the Bd. of Trus. of the Indiana State Univ. for the following work in new Science Hall in said University: Furnishing material and installing plumbing and gas fitting, also separate bids for heating and for additional boilers and other connections, fittings, labor and material relating thereto. John W. Cravens, Secy.

Hastings, N. Y.—The lowest bid opened by the Bd. of Educ., Aug. 15, for erecting a brick school on Farragut Road, is stated to have been submitted by Robt. L. Stewart, for $42,975.

Fairfield, Ia.—The Parsons College is reported to have been destroyed by fire Aug. 19.

Buffalo, N. Y.—Bids are wanted Sept. 2 for ventilating and heating Lafayette High School, Francis G. Ward, Comr. of Pub. Wks.

New York, N. Y.—The following bids were opened Aug. 15 by C. B. J. Snyder, Supt. of School Bldgs., Dept. of Educ., for the general construction on School 65, Boro. of Bronx: Thos. Dwyer, $188,000; Luke A. Burke, 401 W. 59th St., $181,750.

For general construction of School 110, Boro. of Manhattan: Patk. Sullivan, 389 Broome St., $226,000; Wm. & Thos. Lamb, $239,891.

For sanitary work, Morris High School, Boro. Bronx: Kirchhoff & Brown, 166 E. 82d St., $36,350; Jas. Fay, 205 E. 51st St., $35,545; Edw. J. Renehan, $36,000.

For sanitary work (contract No. 2), New High School of Commerce, Boro. of Manhattan: Kirchhoff & Brown, $29,735; Jas. Fay, $30,640; Edw. J. Renehan, $31,300.

For installing electric light wiring, etc., Morris High School: Fredk. Pearce, 18 Rose St., $28,886; Commercial Const. Co., $29,350; T. Fred. Jackson, $29,995.

For installing electric elevators, Wadleigh High School, Boro. of Manhattan: Otis Elevator Co., $10,850.

Brooklyn, N. Y.—The following bids were opened Aug. 15 by C. B. J. Snyder, Supt. of School Bldgs., Dept. of Educ., New York City: Erecting new building, etc., School 91, Boro. of Brooklyn: Francis Sullivan, $58,900; Thos. Dwyer, $65,250; Peter Cleary, $66,000; George Hildebrand, $67,581; Rutan & Henningham, $61,667; Chris. J. Kenny, $63,800; Patk. Sullivan, $61,000.

For erecting school 130, Boro. Brooklyn: John H. Goetschius, $125,500; Patk. Sullivan, $132,000; Peter Cleary, $115,983; Rutan & Henningham, Manhattan Ave. near Conselyea St., $111,805; Wm. & Thos. Lamb, $121,413.

STREET CLEANING AND GARBAGE DISPOSAL.

North Adams, Mass.—Bids are wanted Sept. 10 for the collection and disposal of garbage for a period of 5 years from Nov. 1, 1902. J. Q. Irwin, Clk. Bd. of Health.

Homestead, Pa.—See "Water."

Oakland, Cal.—The Merchants' Exchange has adopted resolutions favorable to the erection of a garbage crematory.

Utica, N. Y.—Local papers state that the contract for the removal of ashes and rubbish and for the sweeping of paved streets in Utica expires in Oct., and that the City Engr. has prepared new specifications for both classes of work.

GOVERNMENT WORK.

Philadelphia, Pa.—Bids are wanted at the Bureau of Supplies & Accounts, Navy Dept., Washington, D. C., until Aug. 26 for furnishing at the League Island Navy Yard a quantity of boiler tubes, electrical supplies, pipe fittings, etc. A. S. Kenny, Paymaster Gen., U. S. N.

Duluth, Minn.—Bids are wanted Aug. 30 for connecting Presque Isle breakwater with the shore, Marquette Bay, Mich. Capt. D. D. Gaillard, Corps of Engrs., U. S. A.

Navajo Agency, New Mex.—Bids are wanted Sept. 11 at the Dept. of Interior, Office of Indian Affairs, Washington, D. C., for constructing a water system at the Navajo Agency school. W. A. Jones, Comr.

Chicago, Ill.—Bids are wanted Sept. 24 at the Treasury Dept., Washington, D. C., for the interior finish and completion of the Post Office at Chicago: Henry Ives Cobb, Archt., U. S. Gov. Bldg. at Chicago; Treasury Dept., Washington.

Newport, R. I.—Bids are wanted at the Bureau of Supplies & Accounts, Navy Dept., Washington, D. C., until Aug. 26 for furnishing, at Naval Training Station, labor and material for building auditorium, laying pavements, completing breakwater and extending sea wall. A. S. Kenny, Paymaster Gen., U. S. Navy.

Cleveland, O.—Bids were opened Aug. 15 by Maj. Dan C. Kingman, Corps of Engrs., U. S. A., for dredging in Cleveland Harbor, and the bid of L. P. & J. A. Smith Co., Cleveland (lowest bidders), which was as follows, was recommended for award: 18¾ cts. per cu. yd. for approximately 200,000 cu. yds. of work to be done; board of inspectors per day, per man, 50 cts.; total, $37,000.

Erie Harbor, Pa.—Maj. T. W. Symons, Corps of Engrs., U. S. A., Buffalo, N. Y., writes that the lowest bid received Aug. 15 for dredging and construction work at Erie Harbor, Pa., was from the Buffalo Dredging Co., Buffalo, at $147,726. The award of contract has not yet been approved by the Ch. of Engrs.

Ft. McKinley, Me.—Capt. A. W. Yates, Q. M., U. S. A., Portland, Me., writes that all bids received Aug. 4 for the construction of a sewer system at Ft. McKinley has been rejected, and that new bids will be asked.

Denver, Colo.—The only bid received Aug. 19 at the Treasury Dept., Washington, D. C., for safety vaults and vault doors at the U. S. Mint, Denver, was from the York Safe & Lock Co., York, Pa., at $88,660 and $93,660.

St. Louis, Mo.—Bids will be received by Capt. W. C. R. Colquhoun, Depot Q. M., until Sept. 20 for repairing the government roadway leading from Springfield, Mo., to the National Cemetery.

St. Louis, Mo.—Bids are wanted Sept. 10 for an iron fence, artificial stone sidewalks, etc., for the U. S. Marine Hospital at St. Louis. Specifications may be obtained from Jas. S. Gassaway, Surgeon, P. H. & M. H. S. (Custodian).

Boston, Mass.—Bids are wanted Aug. 30 for repairs to plumbing in the U. S. Marine Hospital at Boston. R. M. Woodward, Surgeon, P. H. & M. H. S., Custodian.

Charleston, S. C.—Bids will be received at the Bureau of Yards & Docks, Navy Dept., Washington, D. C., until Oct. 11 for constructing a concrete and granite drydock, exclusive of pumping plant and caisson, at the Navy Yard, Charleston. Authorized cost of entire work, $1,250,000. Mordecai T. Endicott, Ch. of Bureau.

New York, N. Y.—Bids are wanted Sept. 8 for repairing dikes at Saugerties. Col. S. M. Mansfield, Corps Engrs., U. S. A.

New York, N. Y.—The following bids opened Aug. 14 by Col. S. M. Mansfield, Corps of Engrs., U. S. A., for dredging in Harlem River, have both been rejected: Morris & Cummings Dredging Co., N. Y. City, Section No. 1, 10,000 cu. yds. at 34.4 cts. per cu. yd.; Section No. 2, 250,000 cu. yds. at 30.4 cts.; R. G. Packard Co., N. Y. City, Section No. 2, at 32 cts.

Fergus Falls, Minn.—The following bids were opened Aug. 18 at the Treasury Dept., Washington, D. C., for the construction (except heating apparatus, electric wiring and conduits) of the U. S. Court House and Post Office at Fergus Falls: J. W. Miller, St. Paul, $61,886, $62,925 and $62,535; Lowenston Bros., Fergus Falls, $69,827; Congress Const. Co., Chicago, Ill., $67,542.

Denver, Colo.—The following bids were opened Aug. 12 at the Treasury Dept., Washington, D. C., for the completion (except certain steel vaults, plumbing, elevators, heating apparatus, electric wiring and conduits) of the U. S. Mint at Denver: A. B. Stannard, New York City, $217,622; J. A. McGonigle, Leavenworth, Kan., $213,432; Simpson & Toogood, Denver, $217,900; Congress Const. Co., Chicago, Ill., $227,326; P. N. Hennessy, St. Paul, Minn., $228,900.

Milwaukee, Wis.—Maj. J. G. Warren, Corps of Engrs., U. S. A., writes that the following bids were opened Aug. 15 for dredging Green Bay Harbor, Wis., 800,000 cu. yds.: A, Duluth Dredge & Dock Co., Duluth, Minn., 14 cts. per cu. yd.; B, Lydon & Drews Co., Chicago, Ill., 15 cts.; C, Saml. O. Dixon, Milwaukee, Wis., 12 cts.; D, Buffalo Dredging Co., Buffalo, N. Y., 17 cts.; E, FitzSimons & Connell Co., Chicago, Ill., 15 cts.

Bids opened at the same time for dredging Menominee Harbor and River in Mich. and Wis. were as follows: *a*, price per cu. yd. for 200,000 cu. yds. sand, clay, mud, etc.; *b*, 20,000 cu. yds. boulders and hardpan: A, *a* 12.9 cts., *b* 48 cts.; B, *a* 15 cts., *b* 68 cts.; C, *a* 14½ cts., *b* 52 cts.; D, *a* 17 cts., *b* 70 cts.; E, *a* 16 cts., *b* 60 cts.

Cleveland, O.—The following bids were opened Aug. 14 by Maj. Dan C. Kingman, Corps of Engrs., U. S. A., for improving Sandusky Harbor, O., by dredging: *a*, Outer bar, 120,000 cu. yds.; *b*, Straight channel, 200,000 cu. yds.; *c*, Main dock, 50,000 cu. yds.; *d*, West dock, 40,000 cu. yds.; *e*, Dock channel rock, 5,000 cu. yds.; *f*, Board of inspector, per day; *g*, total: W. A. McGillis & Co., Cleveland, *a* 25 cts., *b* 14 cts., *c* 16 cts., *d* 28 cts., *e* $6.15, *f* 48 cts., *g* $107,950; Lydon & Drews Co., Chicago, Ill., *a* 24 cts., *b* 16 cts., *c* 20 cts., *d* 20 cts., *e* $7.50, *f* 50 cts., *g* $116,300; Daly & Hannan Dredging Co., Ogdensburg, N. Y., *a* 23 cts., *b* 14 cts., *c* 16 cts., *d* 36 cts., *e* $6.25, *f* $1, *g* $109,250; Jas. Pryor, Houghton, Mich., *a* 23 cts., *b* 13 cts., *c* 23 cts., *d* 40 cts., *e* $6.75, *f* 50 cts., *g* $114,850; Buffalo Dredging Co., Buffalo, N. Y., *a* 20 cts., *b* 20 cts., *c* 20 cts., *d* 20 cts., *e* $8, *f* 50 cts., *g* $122,000; G. H. Breymann & Bros., Toledo, O., *a* 24 cts., *b* 12¾ cts., *c* 18 cts., *d* 30 cts., *e* $6, *f* 50 cts., *g* $105,550; FitzSimons & Connell Co., Chicago, Ill., *a* 23 cts., *b* 15½ cts., *c* 18 cts., *d* 40 cts., *e* $7.75, *f* 60 cts., *g* $122,350; L. P. & J. A. Smith Co., Cleveland, *a* 28 cts., *b* 14 cts., *c* 22 cts., *d* 40 cts., *e* $7.25, *f* 50 cts., *g* $124,850. All recommended for rejection owing to high prices.

MISCELLANEOUS.

Syracuse, N. Y.—Bids are wanted Sept. 2 for improving Onondaga Creek, in accordance with plans and specification on file in the office of City Engr. Frank J. Schnauber, which call for 43,500 cu. yds. of excavation, 800 cu. yds. of embankment, 1,000 cu. yds. of masonry, 250 cu. yds. of concrete, bailing and draining, and 2 acres of cleaning and grubbing. Wm. H. Jones, City Clk.

Philadelphia, Pa.—See "Electric Railways."

Orillia, Ont.—Bids are wanted Sept. 10 for constructing a wharf in the Park, in this city. Fred Gelinas, Secy. Dept. Pub. Wks., Ottawa.

St. Peters, P. E. I.—Bids are wanted Sept. 8 for constructing a new block at outer end of breakwater at St. Peters. Fred. Gelinas, Secy. Bd. Pub. Wks., Ottawa, Ont.; J. B. Hegan, Res. Engr., Charlottetown, P. E. I.

Albany, N. Y.—Bids will be received by Chas. S. Boyd, State Supt. Pub. Wks., until Sept. 2 for dredging inlet to Cayuga Lake and repairing State pier at mouth of such inlet; for constructing retaining walls, sidewalks and curb at approach to bridge over Erie Canal, Watervliet, and for rebuilding vertical and slope walls, and excavating channel of Dry River, in said city; for repairing and improving Castorland dike, between main shore near Castorland depot, and bridge crossing Black River in Denmark, Lewis Co.; for repairing dikes and banks of Chemung River in Elmira; for providing drainage for purpose of conducting waters of Washington and Cemetery creeks in Geneva, from a point beyond termini of said creeks, through towing paths extended of Cayuga and Seneca Canal; for the extension of the towing path of Cayuga and Seneca Canal from its former terminus, southerly along the west shore of Geneva harbor.

Richmond, Va.—The Street Com. has passed favorably upon the plans of the City Engr. for the proposed straightening of Shockoe Creek at the foot of 2d St. Estimated cost, $25,000.

Galveston, Tex.—Local press reports state that the following bids were opened by the County Comrs. on Aug. 11 for the construction of a sea wall: I. Heffron, Galveston, $1,068,066; Parker-Washington Co., San Antonio, Tex., $1,124,022; John W. O'Rourke, Denver, Colo., $1,258,425; B. Lantry Sons, Strong City, Kan., $1,260,937; J. W. Thompson, St. Louis, Mo., $1,269,054; Geo. W. Catt, New York, $1,305,819; R. S. Van Sant, St. Louis, Mo., $1,350,771.

Baltimore, Md.—The Baltimore & Ohio R. R. has made application to the Harbor Bd. for permission to build a pier, 860x160 ft., which is to be used by the North German Lloyd Steamship Co.

New Orleans, La.—Bids will be received by H. B. Speed, Secy. Bd. of State Engrs., until Aug. 28, for about 200,000 cu. yds. of levee work on Fulton Lake levee, in Desha County, Ark.

New Orleans, La.—The Bd. of Port Comrs. has instructed its Engr. to prepare plans and specifications for the erection of steel sheds along the river front at Market and Orange Sts., Picayune tier and Clonet St.

NEW INDUSTRIAL PLANTS.

E. Rothrock, Wellington, Kans., is secretary of a company which will put up a 400-bbl. flour mill for which a 225-H.-P. engine and two 6x16-ft. boilers are needed.

Parke, Davis & Co., Detroit, are making large additions to their electrical and steam plant under the direction of Geo. W. Scott, consulting engineer, The Rookery, Chicago.

Chief Engr. W. J. Harahan, of the Illinois Central R. R., states that the capacity of the power plant for the Memphis, Tenn., shops has not been determined. The plan of the shops shows a 104x243-ft. car repair shop, a 104x155-ft. mill and carpenter shop, a 104x101-ft. blacksmith and tank shop and a 104x152-ft. machine shop.

Pres. W. L. Durst, of the Greenwood, S. C., Cotton Mill, states that it is proposed to erect a second mill with 10,000 spindles.

The Missouri Furniture Co., 1427 Sarsfield Place, St. Louis, will put up a 6-story 60x127½-ft. woodworking shop with a 150-H.-P. power plant. Gerhart Becker, architect.

Margolius & Co., Norfolk, Va., will put up a 75x175-ft. plant, for which a 75-H.-P. engine and 100-H.-P. boiler will be required.

Pres. J. H. Sale, of the Louisville & Portsmouth Fire Brick Co., Louisville, Ky., states that the power plant for its 30,000-brick plant has not been ordered yet.

The Detroit, Mich., Shipbuilding Co. will put up a 75x151-ft. foundry with two 20-ton cupolas and a 40-ton and a 15-ton traveling electric crane.

A. H. Miller, Lewiston, N. Y., is erecting a two-story 40x125-ft. concrete cold-storage building, for which the power plant has not been ordered.

The West Coast Mfg. & Inv. Co., Ballard, Wash., will rebuild its burned plant; capacity, 75,000 ft. lumber and 250,000 shingles.

The Indianapolis, Ind., Abattoir Co. will build an addition to its packing house next fall or spring, but plans are not yet completed.

The Crescent City Stock Yard & Slaughter House Co., New Orleans, contemplates adding to its plant, but the plans are still incomplete.

E. P. Simpson, The Haddock Inn, Toccoa Falls, Ga., will buy a 10-ton ice plant for the Farmers' Cotton Oil & Fertilizer Co., Toccoa Falls; electric power from a local plant will be used.

Otto C. Wolf, 1025 Arch St., Philadelphia, is designing for the Rosenegk Brewing Co., Baltimore, a 3-story 45x90-ft. stock house, a 2-story 40x60-ft. bottling house and a 2-story 20x30-ft. office; a 100-ton refrigerating machine will be installed.

The Wray-Austin Machinery Co., Detroit, is erecting a temporary 45x150-ft. shop for which a 50-H.-P. power plant will be installed.

Frank S. Betz & Co., Chicago, are putting up a building with 58,000 sq. ft. of floor space for manufacturing surgical instruments and will use small electric motors for power.

The Crown Paper Co., San Francisco, Cal., will build a new wood pulp plant, for which about 1,000 H.-P. will be required; the plans are still unfinished.

The Coldwater, Mo., Milling Co. will put up a 40-bbl. mill next month, for which machinery has not yet been ordered.

BUSINESS NOTES.

The Otis Elevator Co. reported on Aug. 15 that it closed orders for 40 hydraulic passenger elevators for New York office buildings during the past week, and for 51 electric elevators for the same city.

C. W. Mouch, of the Indiana Rolling Mill Co., New Castle, Ind., states that its main building is to be 70x200 ft. Two 500-H.-P. Allis engines with boilers have been ordered, and the rolls will be made by the Lewis Foundry & Machine Co., Pittsburg.

Recent sales of Westinghouse gas engines include the following large orders. Philadelphia Bureau of Water, eight 280-H.-P. and two 125-H.-P., to be direct connected to pumps for the high-service fire mains described in this paper on June 14; Logan Natural Gas Co., Lancaster, O., a 650-H.-P. driving a gas compressor; Riter-Conley Mfg. Co., Leetsdale, Pa., two 300-H.-P.; Winchester Repeating Arms Co., New Haven, Conn., two 150-H.-P. and one 165-H.-P. using producer gas; Bradford, Pa., Electric Light & Power Co., a 250-H.-P., being a repeat order; Penn American Glass Co., Alexandria, Ind., a 175-H.-P. direct connected to generator; Lippincott Glass Co., Alexandria, Ind., an 85-H.-P. Pittsburg Plate Glass Co., Ford City, Pa., five of 85 H.-P.

The Steam Boiler Equipment Co., 20 West Houston St., New York, states that since the beginning of the present difficulty in obtaining anthracite coal, it has installed its hydro-carbon system of regulating soft-coal furnaces in hotels, factories and office buildings in cities where smoke inspection is rigid, with satisfactory results in all cases.

The American Bridge & Scraper Co. has been organized by George Nichol and associates of Anderson, Ind., who have bought the plant of the Northwestern Scraper Co., in that city.

The Saginaw, Mich., Sugar Co., the Alma, Mich., Sugar Co., the Lansing, Mich., Sugar Co. and the Naomi Coal Co., McKeesport, Pa., are to install electric power plants for which engines have been ordered from the Ball Engine Co., Erie, Pa. Ball engines for lighting purposes have been sold to Col. W. H. Dewey, Mampa, Idaho, and to the Williams Bros. Co., Detroit.

The West German Portland Cement Co. has been incorporated, with $1,000,000 capital stock, to build works in Lima township, Washtenaw County, Mich. Linus S. Learch and Howard C. Miller, of Detroit, are leading stockholders.

The steam loop and Holly gravity return system is being installed in a large number of power plants at present, some recent orders placed with Westinghouse, Church, Kerr & Co., coming from the Meriden, Conn., Electric Light Co.; the Worcester, Mass., Consolidated Street Ry.; the Columbus, Buckeye Lake & Newark Ry., Hebron; the Boston & Northern St. Ry., Lowell; Boston & Worcester St. Ry., South Framingham, Mass.; Rhode Island & Suburban Ry., Providence; Berkshire St. Ry., Pittsfield; Philadelphia & Reading Ry., Reading; Rockingham Light & Power Co., Portsmouth, N. H.; Michigan Central Ry., Jackson, Mich.; American Smelting & Refining Co., Mexico; Chicago Edison Co., Chicago; Armour & Co., Chicago; American Smelting & Refining Co., Leadville; Atchison, Topeka & Santa Fe Ry., Topeka; American Cigar Co., Richmond; J. B. Stetson, Philadelphia; and the Lake Shore & Michigan Southern R. R., Collinswood, O.

The Alberger Condenser Co., 95 Liberty St., New York, has contracted to furnish the Commonwealth Electric Co., Chicago, a condensing plant to operate with a 7,500-H.-P. turbine-generator. It will be of the high-vacuum type, with 20,000 sq. ft. of cooling surface, and will require a pumping plant embracing a dry vacuum pump with Corliss valves, a centrifugal circulating pump, a hot well with a pump driven by a Corliss engine, and two vertical boiler feed pumps.

The Allis-Chalmers Co. reports the following sales of Reynolds-Corliss engines during July: L. T. Williams & Sons, New York, a 22x42-in.; G. A. Bergland, Milwaukee, a 20x42-in.; Rock Plaster Co., New York, a 22x42-in.; Madero & Rincon Gallardo, Lagos, Mex., a 14x36 in.; John M. Stone Cotton Mills, Starkville, Miss., an 18x48-in.; Combination Rubber & Belting Co., Bloomfield, N. J., a 20x42-in.; Springville Mfg. Co., Rockville, Conn., a 14x36-in.; Lidgerwood Mfg. Co., New York, an 18x36-in.; Brunswick-Balke-Collender Co., Chicago, a 26x48-in.; C. A. McDonald, Chicago, two tandem compounds 14 and 26x42-in.; Keye Bros., Argyle, Minn., a 10x30-in.; Barnet & Record Co., Minneapolis, a 20x42-in.; Cashier Mining & Milling Co., Breckenridge, Colo., an 18x36-in.; McCormick Harvesting Machine Co., Chicago, a 15 and 32x36-in. vertical compound; Griffin Wheel Co., Chicago, a 16x42-in.; International Paper Co., New York, a 22x36-in.; New Orleans Ry., two 38 and 80x60-in. vertical compounds. The month's sales also included several large blowing engines, two large pumping engines and a pair of 438-H.-P. Sederholm boilers for a working pressure of 150 lbs.

The Pittsburgh Gage & Supply Co., Pittsburg, Pa., is overhauling the power plant of the Cadiz, O., Electric Light & Power Co. and installing two 125-H.-P. boilers. The company is also installing a complete oil-filtering system for the Sleepy Eye, Minn., Milling Co.

The New York Continental Jewell Filtration Co. has finished installing a filter plant in the new building of the New York Stock Exchange, one at St. Andrew's Academy, Poughkeepsie, N. Y., and one for the Beaver Valley Water Co., Beaver Falls, Pa. A contract has been just closed for a plant for the new Y. M. C. A. building in New York.

'THE ENGINEERING RECORD.
Volume XLVI., Number 9.

TABLE OF LEADING ARTICLES.

Patents and Ethics 193
Construction of the Lauchensee Dam. (Illustrated) 193
A 27 and 36-Inch Concrete Sewer. (Illustrated) .. 196
The New Covered Reservoir at Newton, Mass. (Illustrated) 197
Notes Concerning Road Construction 198
Heavy Concrete Arches. (Illustrated) 199
Sinking and Testing an Iron Pile 200
The Pacific Portland Cement Company Works. (Illustrated) 201
Power Plant of the Pennsylvania Railroad Station, Pittsburg 203
A Low-Head Water Power Plant at Fumay, France. (Illustrated) 204
Lowering a Heavy Foundation Girder. (Illustrated) 205
The Mechanical Plant in a Newark Department Store. (Illustrated) 206
A Complication of Water Rights 207

The Engineering Record, conducted by Heary C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Patents and Ethics.

From the time the American Society of Civil Engineers began its task of "advancing engineering knowledge and practice and maintaining a high professional standard among its members," it has found in the subject of ethics an inexhaustible field for discussion. Sometimes, to be sure, the word ethics does not appear, but the subject matter has the good old tone, just the same, that a thing of straw always emits when well punched. For instance, the number of times the members of this excellent if somewhat ponderous organization have landed solidly on the solar plexus of "patenting by engineers" cannot be enumerated. If memory does not fail, in the manuscript records of the Society's childhood days, when professional engineers were so few that a plain layman might well think the Golden Rule could cover their relations and have enough good cloth left to hang over the sides, there is an account of the first round of the still-unfinished controversy. The late William Jarvis McAlpine, one of the leading engineers of the time and a man of commanding personality, administered the castigation on this occasion. In those good old days, when personality counted for more than now, the mere fact that an engineer like McAlpine thought one way established that view as firmly as a law of nature in the opinion of the young fry who sat at the feet of the engineering Gamaliel.

But time changes all things and the views held by McAlpine, Jervis, Allen and Kirkwood were abandoned by many civil engineers, although others still held to the tenets of their fathers. Sometimes, to be sure, one of the old school experienced a change of heart: William E. Worthen, for example, as upright a professional man as ever made the word engineer a term of honorable significance, took out a number of patents in the latter part of his life. The increase in the custom has been steady, and has been the subject of repeated comment by members of the Society and others. So The Engineering Record is not surprised at the receipt of a thin pamphlet in which the latest discussion of this branch of ethics is embalmed. The Society, not being itself a professional engineer, does not need to regard the view of professional ethics that says nothing of an engineering nature should be protected by government-granted monopoly and it copyrights its publications. It makes the generous announcement, however, that "reprints from this publication, which is copyrighted, may be made on condition that the full title of Paper, name of Author, page reference, and date of presentation to the Society, are given." So we hastily mention that the paper is entitled, "Is it Unprofessional for an Engineer to Be a Patentee;" the author, Mr. Archibald R. Eldridge; the page, 314; the date of presentation, April 16, 1902. With this libation to the ethical opinions of the Society, it is doubtless safe to proceed.

The author makes this assumption: "Let it be supposed, and the supposition is within the bounds of both possibility and probability, that an eminent engineer, one of the leading lights of the profession, should, by chance, stumble upon a decided improvement in egg-beaters." This seems verging on levity in pages sacred to deep profundity, but much must be excused owing to the author's association with railroad men, whose regard for public opinion was summed up in Commodore Vanderbilt's famous remark. Arguing from his assumption, Mr. Eldridge asserts that the engineering world would not decry his patenting the invention, and then he asks why it should object to his taking out a patent on an improvement in rolling rails, or in a steam engine valve, or in a freight car. In this he touches the exposed nerves of this delicate subject, but, strange to say, in all the discussion of the question there is but one to defend the old position of the McAlpine school, that a patent of any kind is a thing forbidden the civil engineer.

Mr. Eldridge says: "Others may sell the products of their mills and factories; the engineer sells the products of his trained intellect. Wherefore should he then be debarred from selling those products to the best advantage to himself, provided always that they are sold openly and above board, and not sneaked into a piece of work or a contract?" That there is no "wherefore" is the burden of his subsequent remarks, and Messrs. Whinery and Hammatt endorse his statement. To these views there is only Mr. James Owen to lift up the standard of the conservative school. In his opinion, if an engineer in professional practice, as distinct from salaried or manufacturing work, "acquires a patent and uses it there is certainly no moral delinquency, but it lowers the dignity of the profession and lowers its appreciation by the public at large,"

Were it not the fag end of summer and therefore not the appropriate season for unnecessary discussion of such deep subjects, The Engineering Record would feel in duty bound to argue some of the statements by these gentlemen. At present, however, its duty is done in pointing out the facts above mentioned. This journal has spent a quarter century in recording the progress of engineering practice. In its early days patenting by engineers was warmly discussed; to-day, Mr. Whinery says it needs more discussion; a quarter century hence, the arguments will still furnish copy to the Society's printer. Mr. Eldridge feels "confident that the question is now settled, and that an engineer can patent any article he may invent," but he never in his life had a more mistaken belief. So long as human nature remains the same, this subject will be unsettled, for it is one of personal sensitiveness and not of right or wrong, just as some physicians use patented remedies and others will not. But this much may be safely asserted, that any one who makes a useful invention, and does not patent it, is neglecting a legitimate source of revenue. By patenting it, moreover, capital has an incentive to make its value known, and its field of usefulness is thereby increased. Any neglect to do this is simply to stifle the value of the invention, keep it unknown, and thus possibly enable a subsequent inventor to patent it.

Construction of the Lauchensee Dam.

The masonry dam in the upper valley of the Lauch is the fourth structure built by the German authorities in Alsace-Lorraine to increase the low-water flow in the streams of the Vosges Mountains. It proved to be the most difficult and expensive of the four to build, and an outline of the methods followed in the construction is therefore of interest as affording a basis of comparison with American work of a like nature. The following notes have accordingly been condensed from an elaborate article in the "Zeitschrift für Bauwesen," by Mr. H. Fecht.

The mass of the mountain range in the upper Lauch valley is a very dense, glassy graywacke or sandstone, which does not furnish on weathering a sand suitable for building purposes. At a number of points on the ridge of the mountains and also at points in the valley below the site of the dam there is a granite outcrop from which a building sand of quartz grains with a considerable admixture of feldspar can be obtained. The expense of its transportation to the site would bring the cost of such sand up to nearly $7 per cubic yard, which was prohibitory to its use.

The experience gained in the construction of the Vyrnwy dam in Wales, where the geological conditions are similar, showed that the ground sandstone furnished a sharp, durable sand rich in quartz. Surveys in the vicinity of the proposed dam showed that the 30 horse power needed to run the sand crushing plant could be obtained by utilizing the fall of the Lauch just below the scene of operations, where a turbine could be installed. It was estimated that such a plant could furnish a satisfactory sand at about $2.50 per cubic yard, and a hydraulic plant was accordingly installed. Since the valley at the site of the dam is 720 feet above the nearest highway, no work could be done until a road was built to it; this was about 1.85 miles long and its construction was a difficult task.

The dam rests everywhere on sound graywacke, with the seams and joints cleaned out and filled with rich concrete. The structure is curved in plan to a radius of 2,950 feet and its cross-section is shown in the accompanying illustrations. It was designed in the usual German manner, assuming the masonry to have a specific weight of 2.3. The line of pressure with both full and empty reservoir is within the middle third, and at the overflow section at each end the thickness was increased 20 inches. The observations of many years on the elastic behavior of the Vosges dams under water pressure and temperature changes indicated that the water pressure exerted a much smaller influence than the expansion due to warm weather. The fluctuation of temperature in these high valleys hemmed in by naked cliffs amounts to about 100 degrees Fahrenheit. Although it requires a long time for such a large body of masonry to acquire the temperature of the surrounding air, nevertheless the conditions in these valleys are very favorable for such an action. The dams so lie that for most of the day they are exposed to the sun, which also warms the rocky slopes of the vicinity and thus keeps the air at a high temperature. During the winter the downstream face is exposed to the icy east and northeast winds, which are particularly cool at such elevations. Direct observations reveal readily a movement of the masonry under these fluctuations, and such movements, although insignificant, are undesirable and should be reduced to a minimum. For this purpose the downstream face of the

Lauchensee dam has been covered by an earth fill to serve as a heat insulator. Its thickness was fixed by its purpose and by the need of acquiring a stable slope for the stone facing. This earth covering is not expected to prevent all temperature motion, but only a considerable portion of its amount. In the static analysis of the dam under water pressure, the effect of the earth was neglected, but it was considered in the analysis with the reservoir empty.

The reservoir has a capacity of 204,000,000 gallons at the usual flow line, 3.28 feet below the crest. The waste-weirs have been given unusually large dimensions, according to German ideas. Observations from January 1, 1892, to January, 1898, show that the mean annual precipitation at the reservoir is 61.7 inches, and the precipitation on the watershed, which averages 490 feet higher, is therefore assumed to be about 73.6 inches. The watershed has an area of 1,410 acres of which 60 per cent. is wooded. During the same period the annual rainfall at the Alfeld reservoir in the Vosges averaged 79.5 inches, and that on the tributary watershed 121.3 inches; in this case the catchment area is 1,020 acres, and 39 per cent. of it is wooded. The greatest measured runoff at the Alfeld basin was about 0.35 cubic foot per second per acre. If these figures are applied to the Lauchensee basin it is necessary to provide for a runoff of 495 cubic feet per second. It is also necessary to consider the most unfavorable condition which can arise; a warm rain following a protracted storm, with the ground frozen. The melted snow will then run down with the rain, and the ice on the reservoir will become broken up. Under these conditions the runoff may considerably exceed the amount mentioned above and may occur when the waste-weirs are partially choked by ice. In order to ensure full safety under such conditions, four weirs have been provided, two at each end, having a combined capacity of 1,400 cubic feet per second.

Since the only purpose of the reservoir is to supplement the natural low-water flow of the Lauch River, no special designs for drawing off the water are needed. The water is drawn through two openings into a culvert in the dam, which discharges into a paved channel leading to the river; the openings are fitted with sluice gates operated by standards on the upstream edge of the crest of the dam. The lower end of the culvert, outside the dam, is widened and crossed by heavy timbers so as to form a sort of stilling chamber where the velocity of the stream passing into the culvert under a high head is checked.

The only building stone available was the graywacke. While it is very hard and impermeable, it does not possess such an irregular surface when broken as granite. It can be hammered into course stone, but cannot be worked with other tools. The dam was, accordingly, built of cyclopean rubble, some of the stones running as large as ¾ cubic yard, although the most satisfactory size was from ⅓ to ½ cubic yard. Such dimension stone as was needed for the culvert trimmings was granite brought from some distant quarries. The coping, parapet and arches over the waste weirs are concrete mixed in the proportion of one part of Portland cement to eight parts of sand and broken stone.

In order to determine the best mixture for the mortar for the work, tests were made with various brands of Portland cement, black lime, both in lumps and ground, white lime and trass, and with various amounts of sand. The decision was finally reduced to a choice between a mixture of 1 part cement, 1 part lime and 6 parts sand, and a mixture of 1 part lime, 1 part trass and 2½ parts of sand. The strength of these mortars was found to average about as stated in the accompanying tble.

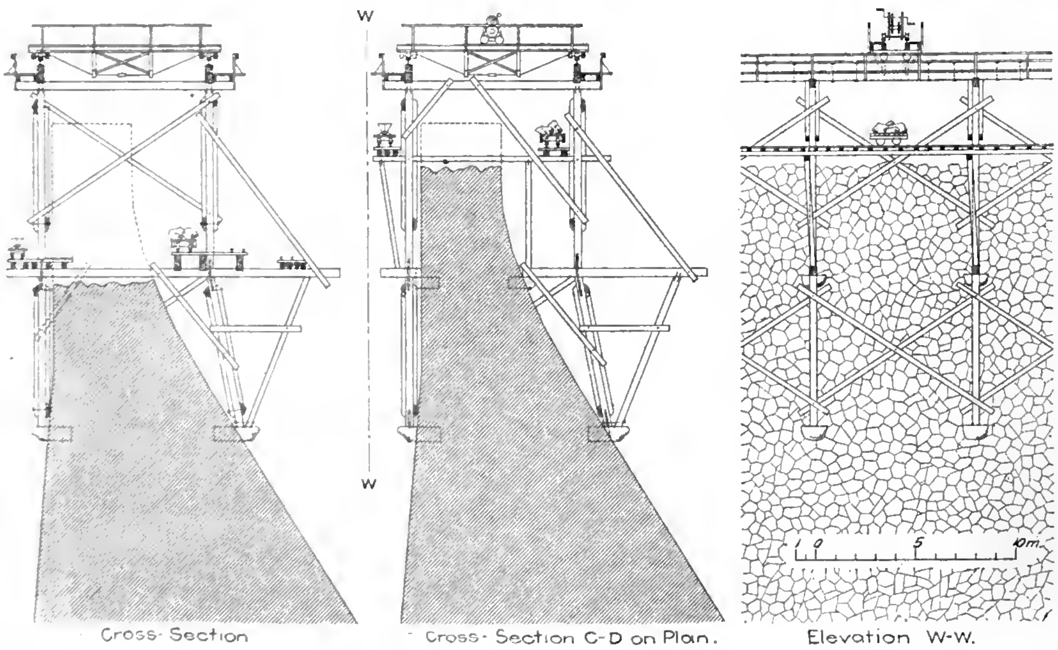
PLAN OF PLANT IN DIFFERENT YEARS.



FRAMING USED IN BUILDING THE DAM.

As to the crushed sand it may be interesting to note that the composition of the materials obtained from the graywacke at Vyrnwy and that at Lauchensee is very nearly the same. The latter is somewhat better, if anything, for it has less magnesia. Both are stated to be rich in silicic acid in readily soluble form, which, on weathering, forms products that have hydraulic properties when combined with lime. The sand therefore acted as a strengthener of the trass, which could be used in consequence in the mortar in a relatively smaller proportion.

Both of the mixtures of mortar above mentioned seemed to be of equal technical value. The trass mortar could be made at a somewhat lower cost and could be used safely for a longer time after it was mixed. This was important at a place where sudden rainstorms might interrupt work many times. Trass mortar which had remained one to two days after mixing could be mixed up again with the addition of some of the binding materials without losing its value. Under similar conditions cement mortar was valueless. The trass-lime mortar was accordingly adopted. The trass was obtained in blocks in car-load lots from Andernach and crushed into sand and stones up to the size of an English walnut.

The experiments with different grades of black lime and white lime showed that the latter, employed in the proportions above mentioned with trass and the excellent sand, answered all requirements as well as the black lime. It also had the advantage that it could be slaked in an open pit and thus be free from danger of injurious subsequent swelling, while its continued usefulness after remaining wet for some time simplified the building operations without introducing any element of danger. The lumps of lime were received in sacks and were slaked in large open pans which were shoved alternately over nine pits.

Examination showed that the rock of the southern side of the valley was much cleft where exposed, while that of the other side was a homogeneous mass. The quarry was accordingly located on this side, 650 to 1,300 feet from the dam so that the blasting would have no injurious effect on the masonry work, and high enough up the slope to allow the stone to be delivered by gravity to the highest part of the structure. In the autumn of 1889 the stripping of the quarry was begun and during the winter two small tunnels 160 feet apart were driven about 165 feet into the hillside. Small branches at the ends and centers brought the total amount of tunnel to 490 feet, and the work was done at a cost of $7.60 per foot. Eight chambers at the ends of the branch were blasted out and charged with 24,200 pounds of coarse black powder having 75 per cent. saltpeter. A dynamite exploder with detonator was placed in each charge and wired to a friction machine 650 feet distant. The chambers were then concreted and the charges fired. About 9,100 cubic yards of stone were dislodged by the shot.

A ditch was dug outside the catchment area on the north slope of the valley and the water of several springs and brooks was thus intercepted and conveyed to reservoir; the ditch is now used to add the runoff of a tract of 250 acres to the reservoir. From the reservoir a 2-inch pipe, with rubber joints for movability, was laid to the mortar mill, lime pits, smithy, the wells at the workmen's barracks and the dam itself. The quantity and pressure of the water were ample for washing the rock surfaces in the excavation for the foundations of the dam, for washing the separate stones used in the masonry, and for keeping the masonry damp so that the trass mortar would harden uniformly.

The sand mill was furnished in 1890 by Brink & Hübner of Mannheim. The main shaft for the sand and mortar machines was 4.8 inches in diameter and was designed to transmit 60 horse power at 120 revolutions per minute. The stone crusher was connected with the shaft by double belts and its flywheel made 200 revolutions per minute. From 12 to 15 horse power was needed by the crusher when working at its full capacity on stone of the usual size. It furnished under such conditions about 6½ cubic yards of broken stone per hour. The material fell into the boot of an elevator, which lifted it about 40 feet to an inclined cylindrical screen of perforated steel plate. The fine particles up to 0.16 inch in diameter fell into a dump car. The parts from 0.16 to 1.6 inches in size dropped into a chute which delivered them to rolls on the floor below, These

Cross-Section of Dam through the Culvert.

rolls were 14.4 inches long and 34 inches in diameter, and made 22 revolutions per minute. They required from 12 to 15 horse power. The product fell into the boot of the elevator, which lifted it again to the screen. The stones in the screen over 1.6 inches in size were raked out and thrown by hand into the crusher. This plant furnished about 2 cubic yards of sand per hour. The rolls had chilled bands and could be easily changed, and the bands could be ground true when worn, without removing the rolls; this was done with an emery wheel making about 1,000 revolutions.

The mortar was prepared in two pug mills. Each was a cast-iron pan 7½ feet in diameter and 1.2 feet deep turning about a vertical axle in its center. This axle was held at the top by a frame, which also carried two rolls 3.5 feet in diameter, 1.2 feet wide and 3,300 pounds in weight. Small plows were attached to the framing so that the mortar would be turned over as the mill revolved. The wheels ground the lime and trass fine when water was added, mixed them well, and formed them with the sand into a very good, uniform mortar. Equal parts of broken trass-rock and lime paste were mixed with plenty of water for a few minutes and the sand then slowly shoveled into the mill. The entire process lasted about ten minutes and furnished nearly ⅓ cubic yard of stiff mortar, which, when cut vertically with a shovel, would retain the smooth surfaces of the cut.

So far as the progress of the work is concerned, the drawings of the framing used during construction and the plans of the plant in 1892 and 1894 furnish more information than a long description. There were eight of the traveling cranes shown on top of the framing, and all stone could be handled directly into place from the cars by them. The mortar was taken to the dam by cars running on an inclined plane having an endless cable driven by the turbine. The whole plant was designed to avoid any handling of material on the masonry itself.

Since the mortar was a purely hydraulic material it was desirable to expose the finished masonry to water as soon as possible. For this purpose, the reservoir level during the winters of 1892 and 1893 was always kept within a short distance of the top of the work. Under these conditions the mortar hardened excellently during the two years, as shown by investigations. Simultaneous experiments with model dams of the same materials, but not exposed to water, showed that the mortar had hardened less and irregularly, and even at the end of another year was not so good. Mr. Fecht considers these results warrant the belief that a new dam which stands several years without exposure to water suffers a detrimental superficial tightening if the mortar is a mixture of lime with cement or trass.

The embankment on the downstream face of the dam was not put in place until after the reservoir had remained filled for four years. In this way it was definitely settled that the masonry was without defects. The joints on the downstream face were then scraped out, a work which showed the mortar to be extraordinarily hard, and pointed with rich cement mortar. The earth embankment was then placed in horizontal layers and its surface covered with a stone pavement.

The dam contains 37,400 cubic yards of masonry, of which 65 per cent. is stone and 35 per cent. mortar. The working force when under full swing included 45 masons, 12 helpers, 27 laborers, 2 overseers and 2 foremen at the works, and 100 to 120 hands with a superintendent and a foreman at the quarry. The average daily task under these conditions was about 120 cubic yards; the greatest day's work was 196 cubic yards.

The cost of the masonry with all appurtenances, including the road, was $220,000, or $5.38 per cubic yard. The earth embankment cost $23,750, making the total cost of the reservoir $243,750. The land was government property. The work was carried out by day labor by the government under the direction of Mr. Bühler, Mr. Fecht being the chief engineer.

A 27 and 30-inch Concrete Sewer.

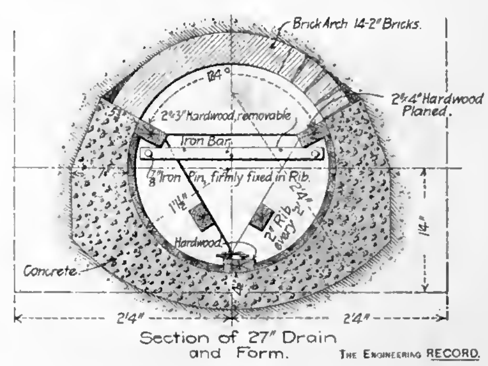
There has recently been completed at Truro, Nova Scotia, a storm-water sewer which differs in some respects from anything previously constructed. In all about 3,200 feet of 27-inch, 30-inch and 36-inch concrete sewer was built, including 6 inlets and 15 catch-basins, also of concrete. The manholes were of brickwork. The centering for the sewer was rather unusual because the concrete was laid in one monolithic mass to and above the center of the sewer, the brick arch for the crown occupying only 124 degrees and 130 degrees of the 27-inch and 30-inch sections respectively. The forms for the inlets and catch-basins were designed so that they might be easily taken apart and put together again. It may be stated that the main reason for using concrete was its cheapness under the given conditions as compared with brickwork.

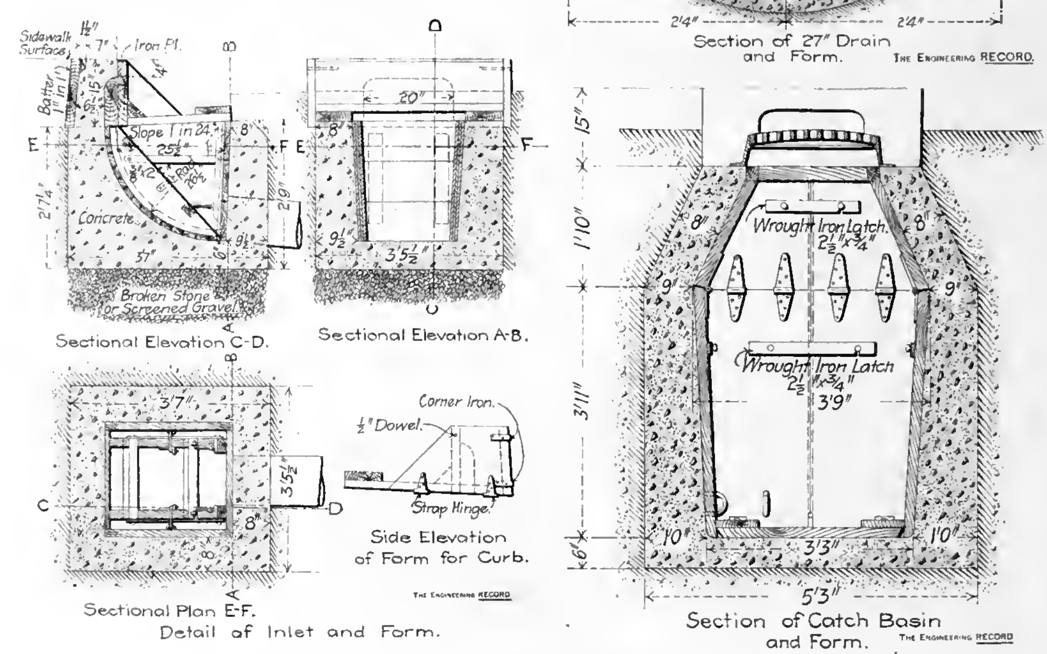
Messrs. Lea & Coffin, of Montreal and Boston, drew up the plans and specifications and were the engineers in charge of the work. In addition to laying this main storm drain, about 3.4 miles of vitrified pipe varying in size from 6 to 20 inches was laid. This was used partly in branches to the storm system, but the majority of it was a new house sewer.

The estimates for the entire work on which the contractors' bids were rated, and the prices paid for the work were as follows, it being understood that all pipes, casting, paving stones, cement and brick were furnished by the town, the contractor furnishing everything else: 19,550 cubic yards earth excavation, 0 to 8 feet deep, at 30 cents per cubic yard; 2,010 cubic yards earth excavation, 8 to 14 feet deep, at 57 cents per cubic yard; 100 cubic yards concrete masonry in trench and foundations, at $5.00 per cubic yard; 502 cubic yards concrete masonry in structures (including furnishing of forms) at $7.00 per cubic yard; 300 cubic yards brick masonry at $6.00 per cubic yard; 100 cubic yards screened gravel in place at $1.75 per cubic yard; 500 lineal feet spruce piles, driven and cut off, at $1.00 per lineal foot; and 5,000 feet, board measure, spruce lumber, placed and fitted as required, at $18.00 per 1,000 feet.

The concrete in the sewer proper and in the catch basins and inlets consisted of 1 part cement, 2½ parts sand, and about 4½ parts gravel passing a 2-inch screen and held on the sand screen. For the concrete in foundation the ratio was 1:3:5. These proportions were determined by experiment in order that the mortar might be slightly in excess of the voids in the gravel. The method of mixing is given in the following extract from the specifications:

"The gravel, which must be clean and free from dust and dirt, shall be spread upon a smooth, tight platform, in a movable frame. This frame shall be of the gauged dimensions for holding the proper amount of stone for a batch, according to the direction of the engineer. The gravel shall be leveled off with the top of the frame and thoroughly wetted. The cement and sand mixed dry upon an adjacent platform, as specified for mortar, shall be uniformly spread upon the top of the stone. The frame shall be lifted off and the material carefully and thoroughly mixed by being turned over with shovels, the men working systematically under the direction of the engineer. If additional water is required it shall be moderately sprinkled on the material from a sprinkler nozzle, care being taken not to wash out the cement or to put on at any time an excess of water."





Details of Construction, Truro Sewerage System.

The concrete was placed in horizontal layers about 6 inches in thickness, and lightly rammed. The usual precautions were taken in joining new work to that which had set, and the whole work was very carefully and systematically carried out.

The centering for the sewer was of 1-inch planed and matched pine boards nailed to ribs of 2-inch planking spaced every 2 feet apart. At the top, along each side of the centering, were placed two 2x4-inch hardwood stringers, between which at every second rib was a 2x3-inch removable hardwood brace held in place by a small hook at each end, which method of attachment was found to serve fully as well as the iron bar and pins originally designed and shown in the section. The centering was made in 10 and 12-foot lengths and in two halves longitudinally hooked together at the bottom and held in place at the top while in use by the hardwood braces. When the concrete had set, the braces were removed and the two halves were shut together, turning about the bottom connection as a hinge, and were lifted out without touching the concrete.

The method of laying the concrete was as follows: The alignment and grade of the invert were given in the usual way from a line stretched over batter-boards placed across the top of the trench. The latter was first excavated so as to leave about 8 inches on each side of the finished structure and to within a few inches of the required depth. Just before the forms were to be placed, the trench was bottomed out to the proper for mand correct depth by the use of a template fixed to the bottom of a rod graduated to feet and tenths. Planks were then laid on edge along each side of the trench as a mold for the outside of the concrete and held in place vertically by iron pins driven down into the ground.

Having prepared the bottom of the trench in this manner, the sections of the centering were then put together on the bank, brushed over with a soft soap solution and lowered onto short pieces of 4x4-inch wood placed across the bottom of the trench. They were thus easily set to line and grade obtained from the batters above. Eight lengths of the 27-inch forms were used, and these were placed end to end in the trench and drawn up tightly together by screw-bolts with hand nuts, making a continuous single form 96 feet long.

The concrete was first filled in up to the top of the vertical side planks, and then similar planks, laid in a sloping position, were placed on top of the vertical ones and held in place at the bottom by projecting strips of iron bearing against the inside of the vertical planks and at the top by small strips of wood nailed to the form. The remainder of the concrete was then put in place.

After allowing the concrete to set a day or two all the sections of the form except the forward one were unbolted, the wooden braces were taken out, and they were hoisted out by two hooks, one under each side stringer, thus causing the two halves to shut together and come out without disturbing the concrete on either side. Starting from the forward form, which, as stated, was left in place, the process of placing the others was repeated. It is stated that the workmen soon learned to perform the various operations with great readiness, and after a little practice the concrete was placed so as to leave a surface as smooth as the planed surface of the boards.

Wherever a good natural foundation could not be secured spruce piles were driven to hard bottom, cut off square, and either gravel or concrete laid on top of this, as the engineer directed. In some cases a simple cradle of planking was laid on the bottom of the trench for a foundation, or the trench was excavated deeper than usual and refilled with either concrete or gravel.

The Centering in Place.

The Completed Invert.

The forms for the inlets and catch-basins are shown in the illustrations, and are so simple in construction that little explanation is necessary. For the catch-basin the form is of 2-inch material. Each side consists of two leaves with beveled edges at the joint. They are held together by 2½x¾-inch wrought-iron latches. The top part of the form, overhanging the rest, is attached to it by means of hinges. The form for the inlet, like the other, is composed of a number of parts held together with hooks and latches. It can be readily understood from a little study of the drawings.

Whenever considered necessary, sub-drains were laid, the joints being filled with jute or wound with suitable cloth. The refilling around sub-drains was of clean screened gravel from ¼-inch to 1½ inches in diameter. In exceptional cases this refilling was covered with a continuous line of jute.

The contractors for the work were Alex. McKenzie and Edward Wilson of Truro. The information from which this article was prepared, including blue prints and photographs, was furnished by the engineers, Messrs. Lea & Coffin.

The New Covered Reservoir at Newton, Mass.

A covered reservoir recently constructed on Waban Hill, Newton, Mass., is 127x165 feet in size, with a depth of about 15 feet, and has a storage capacity of about 2,200,000 gallons. It is the second section of a series of four which have been planned to ultimately surround a central gate chamber. The first section was built in 1890, and is 125x174x15½ feet in size, with an arched brick covering. A full description of the system as laid out at that time was given in The Engineering Record for November 28 and December 12, 1891. The chief point of interest in the new reservoir is the covering, which is of flat concrete-steel construction, built by the Columbian Fireproofing Company, of Pittsburg.

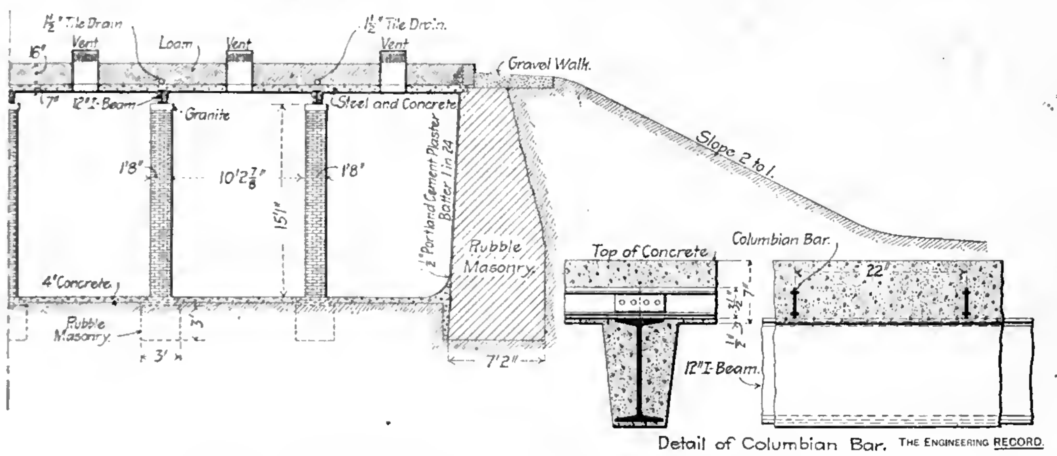
The work was done under two contracts, one for the construction of the reservoir, piers, etc., including all grading of the grounds, and the other for the steel and concrete covering. The specifications for the latter did not limit the bidders to any particular system, but allowed each to submit his own designs for a floor guaranteed to carry a load of 275 pounds per square foot with a factor of safety of 4. This was done in order to insure free competition among the various firms building concrete-steel floors. The contract for the reservoir proper was let to T. Stewart & Son Company for a total of $25,019.75, and the contract for the covering was let to W. H. Maguc, whose bid was on the Columbian system, at 29 cents per square foot, or a total of $6,206. This contract was afterward assigned to the Columbian Fireproofing Company. The foundation for the reservoir is a compact hard-pan and the walls and piers were carried down about 3 feet below the bottom of the reservoir. Only three walls had to be built, the fourth side being one of the walls of the other section, which had been constructed double-faced. Two of the new walls are of rubble masonry 7 feet 2 inches thick at the base and about 3½ feet thick at the top. They are battered 1 in 24 on the water face, which is plastered with a ½-inch coat of neat Portland cement. There is a 6-foot gravel walk around the reservoir, and from the edge of that the embankment has a slope of 2 to 1 until it meets the natural surface. The embankment is made of clayey material put on in layers, wet and well rolled, and afterwards loamed and sodded to correspond with the old sections. The third wall is also of rubble masonry, but faced on the outside above ground with ashlar. It is 8 feet 3 inches thick at the base and about 6½ feet thick at the top, and at some future time will probably serve as the southern wall of another section.

The piers to support the roof are of brick, and are 1 foot 8 inches square, resting on 3-foot rubble masonry bases and capped with blocks of granite. They are spaced north and south 11 feet 10⅞ inches apart, center to center, and 11 feet 8 inches apart east and west. The bottom of the reservoir is of concrete 4 inches thick. Inlet, outlet and drainage pipes are connected with the system in the central gate chamber built in 1890.

The largest items on which the bids for the reservoir proper were based, with the contract prices, are as follows: 5,700 cubic yards of earth excavation at 37 cents; 100 yards of American cement concrete, at $4.75; 250 yards of Portland cement concrete, at $6.50; 1,750 yards of rubble masonry, at $5.75; 190 yards of ashlar masonry, at $20; and 215 yards of brick masonry, at $13.50.

The covering of the reservoir may be briefly described as a monolithic floor of concrete, reinforced with ribbed steel bars, and supported on the tops of 12-inch I-beams, the latter also incased in concrete. The I-beams weigh 31½ pounds per foot and were cut long enough to span two of the 11-foot 8-inch spaces and leave ¼ inch for expansion. The specified loading of 275 pounds per square foot, plus the weight of the flooring, if applied to any large section of the reservoir at once would strain the I-beams considerably beyond a safe limit; and the reason for proportioning the parts in this seemingly unscientific manner was to take care of local loading. There was 150 pounds per square foot of loam placed on the reservoir, and it was estimated that 125 pounds per square foot would be equivalent to the maximum strain which might come on the concrete due to any moving load such as a crowd of people or teams passing over the reservoir. Such a load, however, would be extremely unlikely to occupy a large portion of the reservoir at any one time, so that it need only be used in determining the strength of the concrete-steel filling between the beams.

The flooring itself has a span of 11.9 feet, center to center of the I-beam supports. It consists of 7 inches of Portland cement concrete in which are imbedded 3½-inch Columbian bars spaced 22 inches apart and resting directly on the I-beams. The concrete called for in the specifications was a 1 : 2 : 5 American Portland mixture, but it is stated that as a result of a preliminary test of a section of the flooring 5 feet broad, it was decided to put in a better quality of concrete, and also to make the Columbian bars continuous by means of splice plates. The load applied in this test was not 1,100 pounds per square foot, the full limit required by the specifications, and on account of the time being limited, the test was made at the end of 25 days instead of 30 as specified. It was intended to make a final loading test on the floor when completed, but owing to the inconvenience of obtaining loading material and the lateness of the season, this test was abandoned, and the city engineer relied, in accepting the work, upon the preliminary tests, as well as upon the action of the floor under the heavy loading brought upon it by the teaming of cement gravel and loam during construction.



Details of the New Section of the Waban Hill Reservoir, Newton.

A single line of ventilators furnished by the city was built into the covering along the center of the reservoir. They are somewhat similar to those used on the old section, but of an improved form, admitting the air freely but excluding the light. Lines of 1½-inch horseshoe drainage tiles were laid on top of the concrete directly over each line of I-beams and connecting at the west side of the reservoir with a 4-inch tile drain, while over and around these drains loam to a depth of 16 inches was placed and seeded down. The plans and specifications for this work were prepared by the city engineer, Mr. Irving T. Farnham, and the foregoing description has been prepared from reports and information furnished by him, by the water commissioner, Mr. J. C. Whitney, and by the Columbian Fireproofing Company.

Notes Concerning Road Construction.

The improvement of the highways in the State of New York is under the control of the Boards of Supervisors, and for the last three years delegates from these Boards have met annually to discuss the methods of obtaining the best results from the money available for such improvements, as well as to plan and secure larger appropriations for this purpose. The last convention was attended by 110 supervisors and 50 highway commissioners, representing 40 counties out of the 61 in the State, and the main topic of discussion was the financial problem of improving the highways more rapidly than is now possible. In the four years up to January 1, 1902, during which the State aid laws were in force, 59 miles of road were completed, 109 miles not finished were under construction, 238 miles of road were waiting legislative appropriations as the counties in which they lay had raised their half of the total cost, and 1,250 miles had been more or less investigated by the State Engineer's department. The fact that 20 counties had raised $960,000 to pay their proportion of the cost of 238 miles of new roads, and only a legislative appropriation of an equal amount was necessary to put the work under contract, is a good indication of the appreciation of highway improvements now held in the rural counties of the State. The method employed in building these State aid roads was described substantially as follows at the convention by Mr. Edward A. Bond, the State Engineer and Surveyor, whose department is in charge of the work.

The first step in the preparation of plans for good roads is the survey, which, if properly done, will improve the grades from, at times, 10 to 20 per cent., changing the location of the road to reduce them to 5 or 6 per cent., or better. After the map and profile are once made the engineer carefully locates the grades of the road, so that as nearly as possible the excavation from rock and earth cuts will form the necessary embankment, always keeping in view the proper drainage of the road, allowing for ditches on either side of the finished road to be from 2 to 2½ feet below the crown, with plenty of culverts, either open culverts, box culverts, or cast-iron or vitrified pipe drains, sufficient for the water to quickly flow away in case of heavy rainfall or sudden winter thaw.

In laying the grades the engineer does not necessarily seek to find long continuous grades of a given percentage, but permits undulating grades, always bearing in mind, however, to make the percentage of the grade as low as is consistent with the surrounding conditions. The roads are graded for receiving the macadam surface, varying from 12 to 16 feet in width, and under unusual circumstances they are sometimes for short distances made 20 feet in width. The lower surface is graded to conform to the exact crown of the road when finished, and is graded so at all times to be an equal 6 inches below the macadam surface. After being properly graded, a 10-ton steam roller is placed upon it, and it is thoroughly rolled about five or six times, and if this rolling develops soft spots in the earth, this earth is to be removed and other earth put in its place, so that the whole earth surface is of one consistency throughout any given section of the road. At times very deep sand is met that requires a dressing of shale rock or clay to cover it, and also a similar material to provide wings on either side of the macadam to properly hold the macadam surface in place.

In laying the stone for these roads it is customary to select the best native stone in the immediate neighborhood for the lower course. These stones are drawn to an ordinary rotary or jaw stone crusher, and after being crushed are elevated to a rotary screen that separates the stone into three separate grades; one-half to 1 inch in one compartment, and 1 inch to 1½ inches in another, and 1½ inches to 3 inches in another; the screenings from dust to one-half inch in size being kept separate. In a section where there are ledges of rock and knolls of rock cutting to be excavated for easing the grades, often this rock is suitable to be used in the lower course.

When the State first began to build roads the stone from one-half inch to 1 inch was a waste product, but more recently this has been used for the bottom course on the sub-grade, simply stipulating that it should not in any case occupy more than one-third in thickness of the base course. The base course is made of screen stone 1½ to 3 inches in size, and, with the product of one-half to 1 inch, as above described, is put in a course 5¾ inches in thickness, loose. A 10-ton steam roller is then passed over this stone, beginning on either edge, and rolling toward the center of the road, rolling the whole of it about six times, thus knitting the stone together in one compact mass. After this, about one-half inch in thickness of the screenings, as above described, is placed on this stone. The roller is then passed over it five or six times. An ordinary road sprinkler is then used ahead of the roller, and the rolling and sprinkling continued with the addition of screenings or dust where required, until the whole lower course is filled to the surface with screenings, making one compact mass 4 inches in thickness when finished.

The top course is formed of stone from 1 to 2 inches in size. About 2¾ inches of this loose stone are put on the road and the roller passed over them as described in the first course some five or six times, and then screenings are added, as in the first case. Then follows the sprinkling and rolling until the top course is welded into the bottom course and the two are thoroughly filled with screenings, making a compact mass 6 inches in thickness when finished. At some points in the State this top surface has been made successfully of gravel instead of stone, as heretofore described.

The earth wings on the road are usually from

3 to 5 feet on either side, making a 12-foot road either 18 or 22 feet in width from one ditch to the other, as the case may be, and any other road the additional width of the macadam surface. In a dry season of the year, or when the road is first opened after traffic, it is customary to put an extra coat of stone dust or sand about one-half inch in thickness on top of the finished road. The most desirable stone for the top course for these roads is the Hudson River trap rock, and in all sections of the State which it is convenient to reach by canal this is generally specified, unless it is in exceptional cases, where a hard and durable granitic rock is found near the road to be constructed which will answer the purpose.

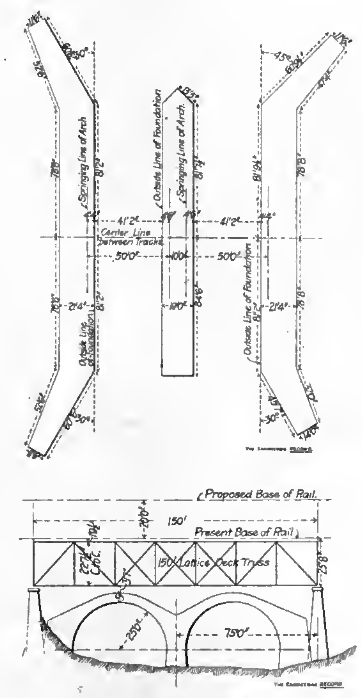
These roads have sustained the ordinary travel of a country district, leading to a populous city, for four years; some of them have been through a section of country having a sand subsoil for part of the way and another portion of the road on the side hill of a precipitous gully of brick clay. Some persons have questioned whether in northern New York roads of the character herein described would withstand the extreme cold weather on a clay soil without being ruined by the action of the frost. Experience has been that a road built as described, with proper care and provided with rapid and successful drainage, will withstand the climate and clay soils of any portion of the State.

The recent experience of the State roads of Massachusetts was summed up as follows by Mr. Charles W. Ross, street commissioner of Newton and formerly State highway commissioner: The style of the road that is being built in different sections at the present time is a very different type from that which was built ten or more years ago. For instance, in many places it has been found from practical experience that from 4 to 6 inches of macadam put on a good gravel foundation will give as good results as could possibly be obtained by putting on 8 or 10 inches, which was formerly the idea. It was evident that the large cost of building macadam roads could not be continued, and it was found by experience that something of a cheaper and yet a durable nature must be obtained. For instance, if a side street in a city has a good gravel foundation it can be covered with from 2 to 3 inches of crushed stone, put on in layers and thoroughly rolled, and give a good result. In many cases such a road is just as satisfactory as one covered with from 4 to 6 inches. When the amount annually appropriated by a city or town is small, it is a hard problem to solve—to know what to do to give the best results with the least amount of expenditure.

The heavy storms which come so often in New England do an immense amount of damage to our roads, and one heavy shower last summer damaged the streets of the city of Newton to such an extent that it would have cost at least $20,000 to put them in the condition that they were in before the storm. As these storms are so liable to occur, it has taught the authorities to look for something more durable that will stand the severe storms of the spring and summer. There have been a great many experiments made in regard to a new mixture of concrete or bituminous macadam, and roads of this material are being built in many parts of the country at the present time. Mr. Ross' experience leads him to believe that in a short time many streets will be covered with a coating of bituminous macadam, which will insure them against the action of the weather, and they will not be affected either by freezing or thawing. While the loss of fine material from the road after a shower is very great, there is also the additional expense of cleaning out the drains and catch basins that have been filled with this material, which is washed from the surface of the streets. It clogs the drains and goes from there into the small streams that lead to the river, and these must be kept cleaned at a great annual expense. If these roads could be surfaced with a less expensive material than asphalt, and yet give a smooth and lasting surface that would not be as slippery in the winter, or even in the summer when it is wet, and would insure it against the action of the high winds that sweep so much of the fine material away during certain seasons of the year, the experiment would be well worth trying.

Heavy Concrete Arches.

Some months ago an esteemed British contemporary, which will long be remembered by Americans as advising foreign engineers visiting the Chicago exposition to carry revolvers although Indians no longer infested that city, announced that a 200-foot concrete arch was under construction across the Vermilion River. This item had a considerable circulation and The Engineering Record has accordingly been to considerable correspondence to ascertain the facts concerning this remarkable structure. The report was finally traced to the Peoria & Eastern Railway Company, but not in its magnified form. As will be seen from the accompanying diagrams, the structure is simply a double 50-foot concrete arch bridge with no special feature about it except that it is under a 68-foot fill which requires a greater thickness of arch width than is ordinarily used with such a span. The arches replace a 150-foot lattice deck bridge carrying a track 20 feet below the proposed rail base of the reconstructed line. The engineer of the structure, Mr. M. A. Neville, sent The Engineering Record a copy of the specifications governing the work, from which the following notes have been taken.



HEAVY CONCRETE ARCHES.

It will be noticed in the diagrams that the arch is 5 feet thick at the crown and has a radius of 25 feet. The abutment at the springing line is 13 feet thick and the central pier is 10 feet thick. The concrete for the arch and spandrel walls is a mixture of 1 part of Portland cement, 2 of sand and 5 of stone broken to pass a $1\frac{1}{4}$-inch ring, while the mixture for piers abutments and wing walls is 1 part cement, 3 of sand and 6 of stone broken to pass a 2-inch ring.

"Hand-mixed concrete shall not be made in batches of more than one yard in each batch. The proper amount of the several kinds of material shall be measured in some way which is entirely satisfactory to the engineer or inspector in charge of the work, so that they may be satisfied that the requisite proportions of each kind of material are delivered for each batch of concrete. Satisfactory methods of measurement will be the use of headless or bottomless barrels for measuring sand and broken stone; the use of boxes into which the sand and stone may be cast and leveled off, (the boxes then being removed); or the use of square and uniform-size wheelbarrows, expressly designed for the purpose. The measurement of sand and broken stone in the ordinary shallow, round-bottom wheelbarrow will not be considered satisfactory, and shall not be permitted.

"The detail of mixing concrete by hand shall be generally as follows: The proper amount of sand shall be measured out and spread upon the concrete platform, and the proper amount of cement shall be delivered and spread upon the same, the sand and cement shall be turned over dry, either by means of shovels or hoes until they are evenly mixed. They shall then be wet and mixed into a rather thin mortar, and shall then again be spread into a uniform and thin layer upon the concrete platform. The proper amount of concrete stone (the same having been previously drenched with water) shall be spread upon the mortar, and the whole shall be turned over at least twice, either by shovels or hoes before it is loaded into the wheelbarrows; or in any other way taken to be placed into work. In wetting the mixture of sand and cement to make the mortar, and in wetting the subsequent mixture of stone, sand and cement (if necessary), a spray or sprinkler shall be used. The water must not be dashed upon the mass in buckets or large quantities, or by means of a jet. The inspector shall insist that the resultant mixture of sand, cement and stone, is as nearly as possible uniform in character, the mortar being equally distributed through the mass of stone. The inspector shall also see that the mixture is neither too wet nor too dry. It should be of such a consistency that when thoroughly rammed it will quake slightly, but it should not be thin enough to quake in the barrow, or before ramming.

"Machine mixed concrete shall be made of the same general consistency as the hand mixed concrete above specified. Proper precautions shall be taken to see that the requisite proportions of the different ingredients are used. If machines are used which are not provided with devices to deliver each of them, the process of making the concrete shall generally be as follows: The proper amount of sand, cement and stone for a batch not to exceed one yard of concrete shall be delivered on the platform, and roughly mixed together so that when the dry mass is cut down and delivered to the mixer by means of shovels, proper amounts of each of the ingredients are handled in each shovelful. It will not be regarded as a satisfactory process to deliver crushed stone, sand and cement at random to the mixer, without taking some special means as above described, to insure the delivery of the proper quantity of each ingredient as nearly as may be simultaneously.

"Concrete facing shall be composed of 1 part Portland cement and $2\frac{1}{2}$ parts sand, and shall have a thickness of at least 1 inch on all arch soffits, arch faces, abutments, piers, spandrels or other exposed surfaces. There must be no definite planes or surface of demarkation between the facing and concrete backing. The facing and backing must be deposited in the same layer, and be well rammed in place at the same time. No plastering will be allowed on the exposed faces of the work, but the inside faces of spandrel walls covered by the fill may be plastered with mortar having the same composition as specified for facing.

"The concrete for arches shall be started simultaneously from both ends of the arch, and be built in longitudinal sections wide enough to constitute a day's work. The concrete shall be deposited in layers not more than 6 inches thick, each layer being well rammed in place before the previously deposited layer has had time to set partially. The work shall proceed day and night, if necessary, to complete each longitudinal section. These sections while being built shall be held in place by substantial timber forms, normal to the centering and parallel to each other, and these forms shall be removed when the section has set sufficiently to admit of it. The sections shall be connected as specified above, and also, if in the opinion of the engineer it is deemed necessary, steel clamps or tie rods shall be built into the concrete."

Sinking and Testing an Iron Pile.

In Hoboken, N. J., at the foot of pier C in the North River, a cylindrical caisson was sunk last Spring to a depth of 97 feet below mean high tide. It was made of cast-iron sections 6 feet in external diameter, 2 inches thick and 6 feet high, with inside flanges bolted together with red-lead and rubber gaskets. Around the lower or cutting edge there was an inside horizontal ring of 1-inch pipe with 3/16-inch perforations ¾ inch apart on the under side. Three 1-inch vertical pipes were connected to the ring and through them water at 200 pounds pressure was pumped to scour the soil under the cutting edge. The caisson was lowered to bottom in 28 feet of water and sunk by its own weight some distance into the soft mud and silt. Then it was loaded with pig iron on a top platform and was gradually sunk with the scouring jets to a depth of 97 feet through blue clay. This was very soft to a depth of about 75 feet where shells were found, and then became a little harder, continuing with the same general characteristics to rock at a depth of 267 feet, as determined by test borings.

As the caisson sunk, sections were successively added to the top until it had a total length of about 108 feet and weighed about 80 tons. A total load of 60 tons of pig iron and the action of the hydraulic jets forced it down at a maximum rate of about 6 feet a day. After sinking was stopped the top was covered by a ribbed cast-iron diaphragm and pneumatic pressure was applied. Men enter the caisson and with a hydraulic jet loosened the core which was ejected in the form of mud by the wet blow-off through a 3-inch pipe contracted to 2 inches at the bottom to prevent the entrance of any objects large enough to cause obstruction. A maximum pressure of about 40 pounds sufficed to make the excavation to a depth of 80 feet where a horizontal bulkhead of two solid courses of crossed 4-inch planks was laid on the ground and braced down by vertical struts up against the under side of the next flange above.

A pair of heavy 12-inch horizontal I-beams were seated on the next flange and supported a platform to carry the pile while it was being assembled. The pile was made with cylindrical cast-iron sections 30 inches in diameter outside, 1½ inches thick and 8 feet high, with inside flanges faced and jointed with red lead and rubber gaskets and having twelve 1¼-inch bolts in each. The lower section terminated in a hollow conical steel casting 4½ feet long with a 6½ inch vertical hole through the 8-inch point. Around the outside of the cone were three turns of a helicoidal flange about 4 feet in diameter and 1¾ inches thick which acted like a gimlet thread to draw the pile down when revolved. There were 3x5-inch rectangular openings through the sides of the cone between the turns of the flange. Two inside vertical pipes 1¾ inches in diameter were formed by coring out the metal of the thickened wall on opposite side of the cone, and terminated near the point with downwardly inclined orifices ½ inch in diameter through the outer walls. These pipes were continuous with a similar pair integral with the walls of each upper section of the pile and formed two tubes reaching to the top of the pile, through which hydraulic jets could be forced if necessary.

The circular opening in the flanges between the point and the lower section of the pile was closed by a ribbed cast-iron horizontal diaphragm in two semi-circular halves which rested on the upper side of the flange. They were braced down against the flange by a pair of inclined pieces in the same vertical diametrical plane. Their feet were close together on opposite edges of the joint and their heads abutted against angle-blocks under the next flange above and were connected by a horizontal strut.

This was hinged on the under side of the middle in such a way as to make a toggle joint which could be broken by pulling up on a vertical rope attached to the middle of the strut and carried to the top of the pile. By operating this rope the braces could be removed and the two parts of the diaphragm hauled up without the necessity of descending in the pile to the bottom.

The pile was assembled, section by section, by a derrick on the pier through which the caisson had been sunk. The lower eight sections were rough castings finished on the flanges only, but the upper sections were turned outside and passed through two horizontal cast-iron guide rings at different heights, which were L-shaped in cross-section and were bored to a close fit. They were secured by triangular frames bolted to the caisson flanges and were eccentric with the caisson. The cylinder extended through packing rings in the horizontal diaphragms which closed the caisson and formed the top and bottom of its air lock and gave it solid bearings to align it and prevent springing and air leakage. The packing rings had been bored to 1/32 inch clearance, but as the pile sections were turned separately and did not match perfectly at joints there were slight offsets there which would not clear the rings and the latter were removed and reamed out ¼ inch larger.

When the pile had been built up above the top of the caisson it was lifted by a wrecking derrick, the platform on which it had been supported was removed, and it was allowed to sink into the mud, which it penetrated about 11 feet by its own weight only. Horizontal timbers were clamped across it just above the top of the caisson and pig iron was loaded on them, and the pile, being intermittently screwed down, sunk at a maximum rate of 6 feet a day which gradually diminished as it went deeper until at a penetration of 113 feet below mean high water three revolutions under a 30-ton load produced no penetration.

A cap bolted to the top flange of the upper section of the pile had a vertical axis with bearings in the horizontal top and bottom plates at the center of the horizontal reaction strut. This was rectangular in cross-section, made with four angles latticed, and was 17 feet long, 3 feet wide and 2 feet deep. The ends had on opposite sides double-flanged bearing plates on vertical guide beams which permitted it to move up or down with clearance, but would not allow it to revolve on the axis of the pile. The pile, cap and loading revolved freely on a common vertical axis. There was keyed to the cap, inside the strut, a wide thick horizontal ratchet wheel which was engaged by two pawls on opposite sides, pivoted to horizontal connecting rods from the pistons of two hydraulic cylinders about 1 foot in diameter and 2 feet long, which were mounted inside the horizontal strut and operated by a pump on the pier. The cylinders were a little inclined to the axis of the strut so that their axes were nearly tangent with the circumference of the ratchet wheel and the connecting rods and pawls were clamped to the ratchet wheel by top and bottom plates which engaged vertical flanges on the inner edge of the circumference of the wheel and slipped freely over it.

Above the upper bearing in the strut the pile cap had a horizontal flange about 3 feet in diamter, on which, after the pile had been driven 113 feet, there were supported two transverse I-beams carrying two spare sections of the caisson with their axes coincident with that of the pile. Their combined weight was about 17,000 pounds, and, being supplemented by pig iron piled inside on a floor laid on the lower flange, helped to sink the pile 10 feet farther when screwing was resumed. The hydraulic apparatus turned the pile at a speed of about one revolution in ten minutes. This caused a penetration of from ⅜ inch to 4 inches per turn and was maintained from half an hour to eight or ten hours at a time, careful observations being made and recorded. At first under the initial load of 10 tons, the pile descended as fast as 6 feet per day, but this rate rapidly decreased and the penetration was very slow and difficult at last, when it attained a final depth of 123 feet and the twisting ceased and experiments were continued on the bearing power of the pile. On August 16 the pile was stationary under a load of 37 tons. Then an increment of 5 tons was added and it immediately cominches to sink at the rate of from 0.01 to 0.02 inches in twenty minutes. In 36 hours it had sunk 11/32 inch and stopped. On August 18 another increment of 5 tons was added bringing the total load up to 47 tons and a settlement of 0.015 inch was observed in twenty minutes, and was continued for some time after at the same rate.

The tests are being made under direction of Mr. C. M. Jacobs, chief engineer for the western division of the proposed Hoboken-New York and Long Island tunnel of the Pennsylvania Railroad Company. Mr. J. Forgie is his principal assistant, Mr. A. D. Barrett is the superintendent and the caisson and pile were sunk by Mr. C. C. Lovejoy.

The American School of Correspondence, Boston, Mass., has recently completed an arrangement with the Armour Institute, of Chicago, whereby students of the former school are admitted to the classes of the latter without further examination, and their work counts towards a B. S. degree. This will enable such students to pursue at home part of the work required by the Armour Institute for a degree and will doubtless be of assistance to young engineers, draftsmen, and others in securing a technical education. The American School of Correspondence will soon remove its office and entire force of teachers to Chicago.

Tree Planting on the watershed of the Wachusett reservoir at Clinton, Mass., has been carried on recently under the direction of the Bureau of Forestry of the Agricultural Department, and it was recently announced that similar work will be undertaken on the watershed of the Woonsocket, R. I., storage reservoir.

The Pacific Portland Cement Company's Works.

By Watson Vredenburgh, Jr., C. E., 32 Broadway, New York.

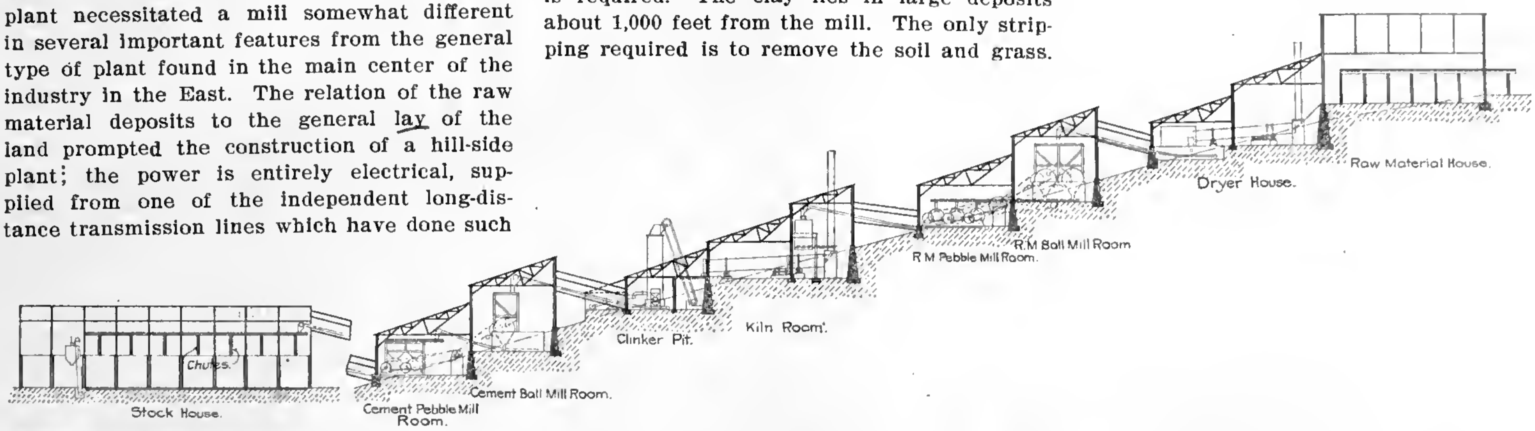
The extreme West has recently begun to take an active part in the development of the cement industry of the country and already a number of plants are projected and several in the course of construction. The plant of the Pacific Portland Cement Company, situated at Suisun, Solano County, Cal., has been under construction for the past year and commenced operation on August 1, 1902.

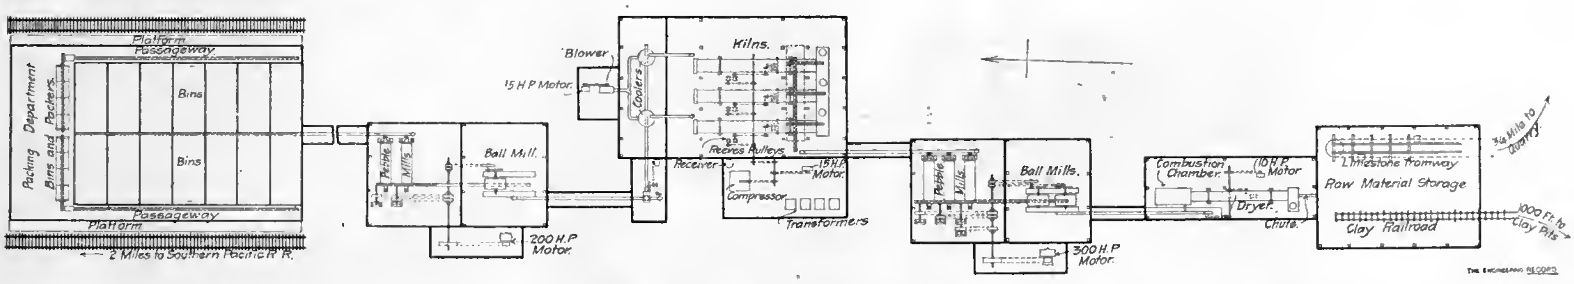
The local conditions surrounding the deposits of the raw materials at the site of this plant necessitated a mill somewhat different in several important features from the general type of plant found in the main center of the industry in the East. The relation of the raw material deposits to the general lay of the land prompted the construction of a hill-side plant; the power is entirely electrical, supplied from one of the independent long-distance transmission lines which have done such notable work on the Pacific Coast, and the fuel for the burning and driving is obtained from the California oil fields. These features make the plant unique in character and an endeavor will be made to describe it under the several most important essential features entering into the successful operation of such a plant and to describe its construction in general.

The company's property comprises approximately 800 acres of land, of which about 300 acres is limestone and the remainder being principally clay deposits. The mill is situated two miles from the Southern Pacific road, and by this route is about 50 miles from San Francisco and 40 miles from Sacramento.

In the selection of the immediate location of the mill the nature of the ground between the quarry and the railroad had to be considered, and, as constructed, the mill stands on the first of a series of foot hills which rise higher and higher to the north. These features have enabled a gravity layout to be made from the quarries through the several stages of manufacture to the stock house, with the two exceptions of the elevation of the clinker to coolers and the use of several elevators in the packing room of the stock house. The connecting railroad from the mill to the main line runs perfectly level for the entire two miles, excepting a very slight rise to the stock house situated at the foot of the slope.

The limestone quarry is situated at a distance of three-quarters of a mile from the mill and is worked from an open face in which the rock comes to the surface so that no stripping is required. The clay lies in large deposits about 1,000 feet from the mill. The only stripping required is to remove the soil and grass.





The Works of the Pacific Portland Cement Co., Suisun, Cal.

The character of the raw materials is shown from the following set of typical analysis, both from material dried at 212 degrees Fahrenheit.

Analysis of Limestone.

Ig. loss	43.74
Silica (SiO_2)	.41
Iron and Aluminum ($Fe_2O_3Al_2O_3$)	.56
Calcium (CaO)	54.86
Magnesium (MgO)	.21

Analysis of Clay.

Ig. loss	9.07	
Silica (SiO_2)	58.44	
Iron and Aluminum ($Fe_2O_3Al_2O_3$)	26.50	7.55 Fe_2O_3; 18.95 Al_2O_3
Calcium (CaO)	1.70	
Magnesium (MgO)	1.88	
Alkali (K_2ONa_2O)	1.56	

The finished cement showed the following analysis, physical and tensile strength tests:

Analysis of Cement.

Silica	22.51
Iron and Aluminum	11.13
Calcium	64.06
Magnesium (MgO)	.99
Sulphuric Anhydrite	1.01
Alkali	.54

Physical Test of Cement.

Initial set	2 hrs.
Set hard	6 hrs. 20 min.
Hot water	O. K.

Tensile Strength Neat Cement.

3 days	290 lbs.
7 "	645 "
28 "	795 "

The power for the entire plant, including the water and oil pumps is electrical; the crusher at the quarry also has its own motor and the ice plant used in connection with the company's boarding house has an independent motor. The power is furnished from the Bay Counties Power Company, which operates its lines of long-distance electrical transmission from Oakland to Colgate, a distance of 152 miles. This power is furnished at 60,000 volts and it is then transformed in the power house of the mill to voltage as required. The power company has two complete lines on independent poles so that the danger of a break down on the lines is reduced to a minimum. A great economy in the distribution of power is anticipated, due to the fact that when any individual machine is shut down its motor is also shut down, and as the power is a direct purchase this means a direct economy.

The power room of the plant is situated alongside the kiln building and directly connected with it. It contains the necessary transformers and switchboards from which the current is distributed to the various motors throughout the plant. In this room a 75-kilowatt motor drives a line shaft, which in turn drives an air compressor for supplying air to the kiln-burning apparatus and also the main shaft driving the kilns. Provision has also been made to install a 100-horse-power engine and boiler to be used as auxiliary power for driving the kiln shaft in the event of an accident to the electrical power. The motors for the plant were supplied by the General Electric Company and the compressor by the Compressed Air Machinery Company of San Francisco.

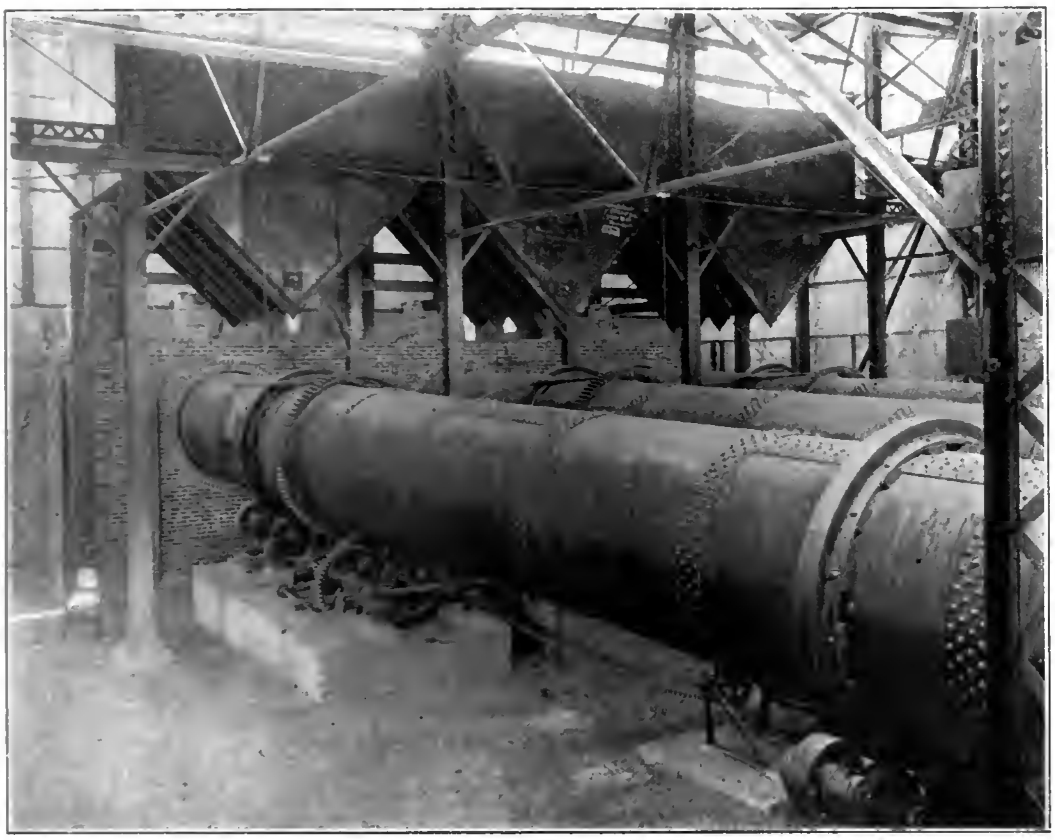
The fuel oil is delivered to the plant from the California oil fields in tank cars. An oil spur is so arranged that two cars can be unloaded at one time. The oil flows by gravity into a tank placed below the rails, and from there is pumped to the elevation of the floor of the raw material house, where storage is provided for 75,000 gallons. From these tanks the oil is fed to the kilns and dryer by gravity.

The accompanying diagram gives a general plan and elevation of the works, showing the relation of the various buildings with their machinery layout, which will be described in the order in which they are employed in the manufacturing processes.

The dimensions of the buildings comprising the plant are as follows: Raw material storage, 60 x 80 feet; dryer house, 30 x 85 feet; raw material ball mill room, 51 x 42 feet; tube mill room, 51 x 46 feet; kiln room, 71 x 69 feet; clinker pit, 41 x 69 feet; cement ball mill room, 42 x 51 feet; cement tube mill, 46 x 51 feet; stock house, 70 x 144 feet.

at present provides simply a bulk storage for the raw materials. It has been thought desirable to make the necessary proportionate mix of raw materials directly by hand in the raw material house during the preliminary experimental stages of manufacture, and, when the plant is in full operation and the materials thoroughly understood, to install a system of bins and conveyors to eliminate the manual labor. The proper mixture to give the desired composition is dumped directly from the floor of the raw material room into a rotary dryer 5 feet in diameter by 50 feet long, of the ordinary type furnished by the Vulcan Iron Works. The heat for the dryer is obtained from fuel oil and a special combustion chamber forming the end housing has been constructed to comply with the requirements of oil burning; grates, ash pits, etc., have also been provided so that coal or wood can be used. The dryer house also contains a 10-horse-power motor driving a counter-shaft from which the dryer is driven directly by belt.

The material passes directly from the dryer to a 16-inch belt conveyor which carries it to



View in the Kiln Room, Pacific Portland Cement Co.

The working floor of the limestone quarry is 200 feet above the base of the raw material storage house. The limestone is crushed to a 2-inch ring in a Gates crusher as it leaves the quarry, and on leaving the crusher drops into a bin, from which it is automatically loaded into buckets and carried to the mill, a distance of three-quarters of a mile, by means of an aerial bucket tramway furnished by the A. Leschen & Sons Rope Company of St. Louis. The buckets enter the raw material house at an elevation of 20 feet and are automatically dumped.

The clay lies in a large deposit about 1,000 feet from the mill, at a slight elevation above the raw material house. It is handled by means of plows and scrapers, and is loaded directly from scrapers into small dump cars. These cars run by gravity into the raw material house at an elevation of 18 feet and are dumped. The empties are made up into trains and are hauled back by horses.

The raw material house is a single room and

bins over two Krupp ball mills. From these mills the product of the first grinding is taken by a screw conveyor directly to a battery of three tube mills, in which the grinding of the raw material mixture is finished. These ball and tube mills, together with those used at the finishing end of the mill, were furnished by Thomas Prosser & Son, of New York. A 300-horse-power motor furnishes the power for this group of mills and drives a main shaft mounted on concrete piers 10 feet above the floor line of the tube mill room, from which the mills are driven directly.

The ground mixture is received directly from the tube mills on a 16-inch belt conveyor which conveys it to a screw conveyor, which in turn deposits it into the raw material tanks over the kilns. There are three rotary kilns 60 feet long and 6 feet in diameter, made by the Vulcan Iron Works, and mounted and turned in the usual manner. Each kiln is driven from the shaft mounted below the kilns and the speed for each controlled by a Reeves speed regulator. The raw material is stored in a large steel tank mounted above the feed end of the kilns and just in front of the housing. This tank is provided with partitions and a V-shaped hopper bottom for each kiln and was furnished by the Heilman Boiler Works, Allentown, Pa. The material is brought from the tanks by a screw conveyor which feeds it to the kiln through water-jacketed tubes. These conveyors are driven by gears and chain drives from the shaft of the kiln-driving gears and are provided with clutches, making the feeds independent of the kiln motion.

The burned material is discharged directly from the kilns in the form of clinker into the boots of elevators, from which it is elevated into clinker coolers. These coolers are 7 feet in diameter and 32 feet high and are provided with an artificial circulation of air through the center. They were made by W. F. Mosser & Sons, Allentown, Pa., and are of standard pattern as furnished by this company. The air blast is furnished by one 80-inch rolling mill blower made by the B. F. Sturtevant Company, the blower being driven by a 15-horse-power motor directly belted.

The cooled clinker is received from each cooler at its center directly on a 16-inch belt conveyor running through the center of the cooler foundation, and is discharged into a weighing hopper at the opposite end. This hopper weighs the clinker and discharges it upon another 16-inch belt conveyor, conveying it to bins over the finishing ball mill, which is fed from them. The arrangement of these ball and tube mills is exactly similar to that of the raw material rooms and the mills may be interchanged without affecting the layout. They are driven in a similar manner to those of the raw material end, a 200-horse-power motor furnishing the power for the main shaft.

The finished product from the cement mills is received on a 16-inch conveyor, which discharges it into a long screw conveyor at the top of the stock house. This conveyor distributes the cement into a series of bins for storage. Provision has been made for a system of conveyors running outside and directly in front of the bins, for bringing the cement to a packing department at the end of the building. In this department the cement will be elevated to bins, from which it will be packed in a series of bag and barrel packers.

The loading of the finished product for shipment can be made from either or both sides of the stock house, and the cars are hauled by the company's locomotives over their own road and delivered to the main line of the Southern Pacific Company, two miles from the works. This connecting road was built and is operated by the cement company.

The elevating and conveying machinery for the entire plant was furnished by the Webster Manufacturing Company, of Chicago; the main shafting, pulleys, clutches, etc., by the Hill Clutch Company, of Cleveland, Ohio, and the leather driving belts throughout by the Page Belting Company, of Concord, N. H.

All the buildings of the plant are of steel frame covered with corrugated iron, the structural steel work for which was furnished by Milliken Brothers, of New York. The slope of the hill-side necessitated the construction of a number of retaining walls, which are built of concrete, as well as all the machinery and building foundations. The entire works were erected by the company, none of the work being done by contract.

The layout of the buildings has been arranged with a view to extension, and an enlargement of the initial plant by the addition of a second unit will be begun as soon as the present works are in full operation.

The main office of the company is situated in San Francisco and its directorate is as follows: Mr. George Stone, president; Mr. Nathan L. Bell, secretary; Messrs. Jas. F. Kilby, Morris Kind and Samuel McMurtrie, directors. Mr. F. H. Lewis, M. Am. Soc. C. E., manager of the Virginia Portland Cement Works at Craigsville, Va., acted as consulting engineer in connection with the writer, who was designing engineer.

The Power Plant for the Pennsylvania Railroad Station, Pittsburg.

As supplementary to the description in The Engineering Record of August 23 of the train-shed for the new depot of the Pennsylvania Railroad at Pittsburg, advantage may be taken of the appearance of a paper by Mr. D. B. Kinch on the power plant for the station, in the July "Proceedings" of the Engineers' Society of Western Pennsylvania. The plant is a centralized, modern one, occupying an isolated building 55x420 feet in ground area, and located to serve both station and yards, the former being a consumer of perhaps 75 per cent. of the plant's output. The paper is reprinted herewith practically in full.

The heating and ventilation of the station, the elevators for both the offices and baggage service, the lighting of the building and yards, the filtering and refrigerating of the drinking water, the building service water, and pressure for fire mains, the entire telegraphic service, etc., are all provided for by the plant, which is duplicated as to the most vital points.

The engine and generator equipment comprises four Westinghouse compound engines, of the standard marine type design. The high pressure cylinder is 17 inches in diameter, the low pressure cylinder 27 inches, with a 24-inch stroke. They are equipped with a Rites governor and have a speed of 200 revolutions per minute. The high pressure cylinder is equipped with a piston valve, double ported, and the low pressure with a slide valve, double ported. The engines are direct connected to 350-kilowatt, 220-volt, two-phase, alternating current dynamos, of the Westinghouse standard type. One engine driven and one motor driven direct-current dynamo, each of 37½ kilowatt capacity, serve as exciters. These exciters also furnish direct current for a number of small motors, used at various points throughout the building on special apparatus for which alternating current motors are not, as yet, provided by the manufacturers in connection with their apparatus.

Current for the storage battery used in connection with the switch and signal installation is also provided from the exciters. These direct current machines also furnish the primary current for 14 Crocker-Wheeler dynamotors, used exclusively for the telegraphic service. The output of these numerous little machines varies from 8 volts on "locals" to 360 volts for duplex and quadruplex service. Battery current for telegraphic purposes is entirely supplanted by the installation of these small sets.

The switchboard panels are of blue Vermont marble, and the board is composed of 13 lower and 9 upper panels, each equipped with main and auxiliary bus bars. Stairways at either end of the board, give free access to the gallery around the upper panels. The lower panels are used for the generating and high tension work and the upper panels for the distribution. It is the intention to run the alternators in parallel, and to this end the synchronizing apparatus is one of the board features. Step-up transformers at a ratio of 10 to 1 are installed to furnish lighting and power circuits to outlying districts.

Ample circuits for series alternating-current arc lamps are provided, and for this work a combination jack and plug board is used. All transformers, as well as rheostats, are placed in the basement directly underneath the switchboard, thus clearing the back of switchboard to an unusual degree. The electrical equipment occupies the entire south side of the engine room, whilst along the north side are located the air compressors, hydraulic pumps, high pressure pumps, small air compressor for thermostatic heat control in the office building, a Scotch yoke air compressor, etc.

The main pumping engine for hydraulic elevators is of the Riedler type, fitted with mechanically operated valves. It has duplex single-acting outside packed plungers, 9½ inches in diameter and 24-inch stroke, steam cylinders 13 inches and 23 inches in diameter with 24-inch stroke. This pump, having a capacity of 1,400 U. S. gallons per minute, against a pressure of 200 pounds to the square inch, when running at about 96 revolutions per minute, with a steam pressure at throttle of 150 pounds. The main feature in the design of this pump was to cut down the floor space to the smallest possible area. For this reason the valve gear was put on the outside of the steam cylinders, in order to get the cylinders close together and do away with the necessity of a passage between the gears, which would have materially widened the engine. The engine frames were made of the double bearing type, with four-part adjustable boxes for all bearing. The entire water and steam end of pump is mounted on a substantial bed plate of box section, insuring alignment and in order to further economize the floor space, the pump end was made of the single acting type, as this would cut down the space required about one-half of that necessary for the double acting pump.

The distinctive feature of this pumping engine is the mechanically operated valves. As the pump is single acting, it was necessary to provide a by-pass so as to enable the pump to run without delivering water when the pressure had passed a certain point. The by-pass valve is operated by means of an air cylinder, which also operates an auxiliary throttle; the steam for running the pump being taken through a small by-pass on the side of this throttle, this by-pass having a valve in it, so that the amount of steam fed to the pump can be adjusted that the pump will not run more than 30 revolutions per minute when running on the by-pass.

The air cylinder for operating water by-pass valve and throttle is controlled by means of a pilot valve operated by an auxiliary governor, this governor only coming into effect when the speed of the engine has dropped to between 20 and 25 revolutions per minute. All of the working parts of governor are central, to eliminate friction; as auxiliary pumps for elevator service two simple direct acting Worthington pumps of 750 gallons each have been installed. These are also used for the night run. The elevator equipment comprises seven high-speed elevators, to travel from train floor to top floor, a distance of 190 ft., and eight direct lift elevators, used for baggage and express service.

For the furnishing of air to the signals and switches as well as for car testing and car cleaning purposes two cross compound vertical Reidler express type compressors are used. Sizes of air cylinders are 14 and 24 inches in diameter with 24-inch stroke driven by a vertical cross compound, non-condensing Corliss steam engine with cylinders 13 and 23 inches in diameter and 24-inch stroke. Each compressor having a capacity of 1,500 cubic feet of free air, net piston displacement, to a maximum pressure of 100 pounds, when running at a speed of 134 revolutions per minute. The air cylinders are mounted above the steam cylinders. Both air cylinders and heads are water jacketed. The air suction and delivery valves are placed in the heads; the suction valves being of the semi-rotative type operated by means of a wrist plate, driven from an eccentric in the same manner as the steam gear. An inter-cooler and an after cooler are provided, the inter-cooler having a volume of about six times the volume of the low pressure cylinder. After the air has been delivered from the high pressure cylinder it is passed through the after cooler so as to remove as far as possible all moisture. It is then delivered to storage tanks located in what is known as the air intake building. This is a separate building of small dimensions directly west of the engine room, and is equipped with storage tanks for air delivery to various points and also with appliances for thoroughly cleansing the air before it is delivered to the suction pipe. A 15-ton electric crane travels the entire length of the engine room, thus assuring valuable aid in case of need.

The boiler room is equipped with Babcock & Wilcox boilers. These boilers are of standard type and are all of forged steel construction, built to carry a working pressure of 200 pounds. The boilers as installed comprise six boilers in three batteries, each unit 300 horse-power, an aggregate of 1,800 horse-power, space being left for an additional battery for future increase. The boilers are equipped with Roney stokers and installed in the boiler room is a Hunt coal and ashes conveyor. Hoppers of 50,000 pounds coal capacity are located over each battery of boilers, and cams are arranged at convenient points along hoppers for dumping the buckets. The conveyor movement is made by a steam engine located in what is known as the annex. The conveyor extends along the top of coal hoppers and passing down the side of west battery runs along the basement floor, and at this point receives the ashes from the ash hoppers under each boiler, and the buckets of the conveyor receive these ashes through an automatic filler located directly under hoppers. The ashes are stored in a large hopper located in the second story of the annex from which chutes are arranged, and the ashes are dumped into cars, which but a few moments before contained the coal. A coal crusher is installed at the lower end of the coal hopper and only used when lump coal is delivered.

Two Cochrane feed water heaters each of 1,500 horse-power capacity are employed in boiler room, and feed water is delivered to the boilers at a temperature of 200 degrees Fahrenheit. All feed water piping to the boilers is of brass and in duplicate.

The chimney is located in the middle of the boiler room and south of the center line. The smoke flues enter chimney on basement level. Suitable dampers under automatic controllers are installed. The chimney is of the Custodis perforated radial brick, and the actual height without base, 240 feet with a base of 13 feet 6 inches high. The diameter of chimney is 9 feet. An 18-inch exhaust pipe extends the whole length of the chimney and extends above at top about 6 feet. This pipe will take care of all the steam exhausted during the warmer months. During the colder months the exhausted steam will be employed in heating the office building. The total weight of chimney, including the exhaust pipe, is about 2,600,000 pounds.

Special attention was devoted to the steam piping system, the view point always being that only partial shut down would result in the case of ordinary repairs or accidents. The piping is all extra heavy, with screwed flanged fittings. Two headers extend along the entire length of boiler room, along the rear of the boilers and about 8 feet above them. Into each one of these headers, is a main from each boiler. This practically duplicates the piping in the boiler room. At the partition wall between the boiler and engine rooms the mains drop to the basement and loop around the engine room. The main steam line runs in about a 4-foot space between the foundations of engines and the wall of building. At each point where a connection is made for engines, valves are placed on either side of this connection in the main line. Thus the connection to any engine can be cut off from the main steam line without interfering with the supply to other points. The exhaust line extends along the center of basement and connects to the exhaust line in the stack and also to a large distributing tank to which the building heating system is connected. A back pressure valve is located on exhaust line leading into the stack. At the west end of the engine room the exhaust line leads up to the roof, connected to exhaust heads. On this line, also, there are back pressure valves.

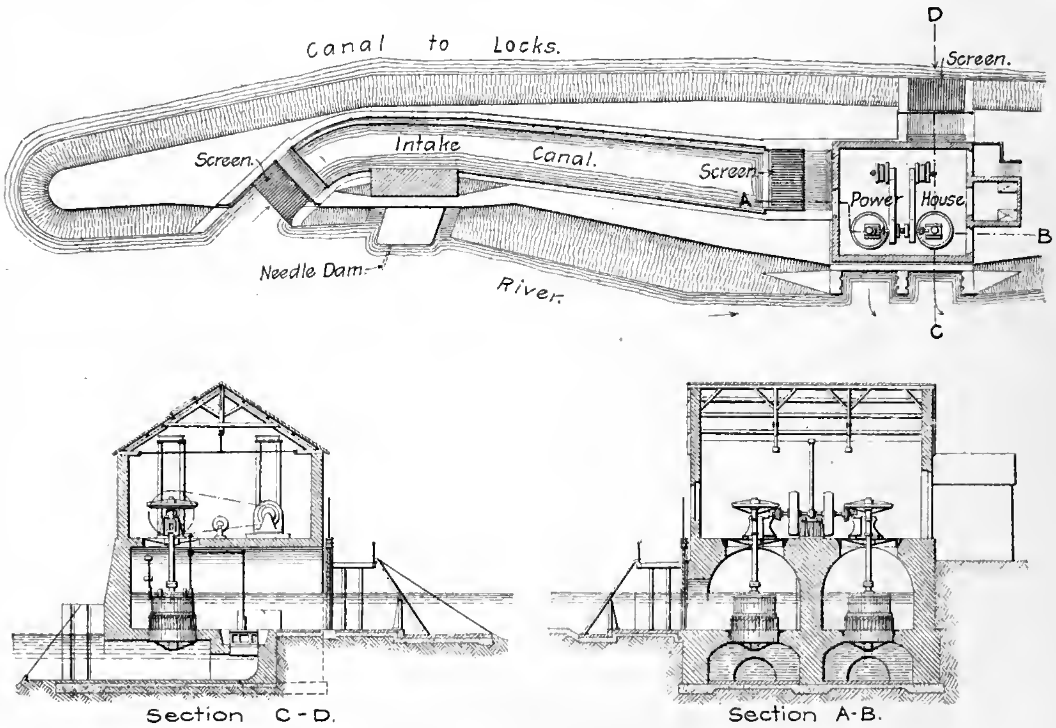
The refrigerating and drinking water plant is located at the partition wall between the engine and boiler rooms on the boiler room side, and is of Carbondale Machine Company's construction. The duty performed consists of refrigeration for two refrigerators for kitchen on top floor, containing approximately 1,000 cubic feet, also refrigerating for main restaurant boxes containing about 4,000 cubic feet, the connecting mains aggregating 1,200 feet. The filtering and cooling of the drinking water supply is for about 125 fountains, located in the offices and waiting rooms. The amount of water cooled is about 750 gallons per hour, with a range of 45 degrees Fahrenheit, from 80 degrees on the intake to 35 degrees to delivery mains. The delivery mains connect with sets of risers in the basement, from which lead the horizontal supply lines to each of the floors connecting to the office outlets, by means of an additional faucet at each washstand. The risers and mains aggregate about 11,000 lineal feet of pipe in supply and return mains. The temperature of the water at the drinking fountains is about 41 or 42 degrees. The method of circulation used ensures equal temperatures at all points, freedom from air in pipes and a continuous supply at all faucets. Stop or regulating cocks are placed at all fountain loops, to provide against excessive pressures due to the height of risers. The pressure at the water circulating pump in the basement of the power plant, a 9x5¼x12-inch duplex, is about 95 pounds. The steam required is about 32 pounds per ton refrigerating effect per hour. The refrigerating machine is of the standard Pontifex-Hendrick absorption pattern of 40 tons capacity, and consists of the generator, analyzer, exchanger, absorber, condenser and brine cooler, with duplicate direct acting single ammonia pumps and duplicate duplex brine circulating pumps. The refrigerant used is fused calcium chloride of 1.250 specific gravity. This substance is circulated through coils in refrigerators, and very low temperatures are possible. The location of refrigerating machinery in power house being essential, and the limited available space necessitated the placing of this apparatus in a space of about 8x30 feet and on three different levels. The machine proper standing on a platform of steel construction of 200 square feet, 12 feet above the power house floor. The cooling and brine storage tanks, with ammonia pump, on the main floor directly underneath, and the water circulating pump and filters below in the basement.

A Low-Head Water-Power Plant at Fumay, France.

A factory for the manufacture of cooking utensils, warming apparatus and general household articles, occupying about 6 acres at Fumay in the department of Ardennes, France, is now supplied with power from a low-head water-power plant supplemented when necessary by a steam plant and all connected on an electric system of distribution. The works were originally operated from a single steam engine with belt and shaft transmission, and as they grew in size, additional steam engines were added, until it was decided to rearrange the power facilities and the electric system of power transmission was adopted. Near the works, which are on the River Meuse, is located a dam required in connection with a lock for the transportation of boats around a fall in the river. Rights were obtained to utilize the flow of surplus water, which, being of low head, comprehended the control of a large discharge. During periods of high water or of stoppage from ice, the water power would prove insufficient for the needs of the works and an auxiliary steam engine driving an electric generator was accordingly installed.

The dam furnishes at low-water a discharge of 705 to 1,060 cubic feet per second under a fall of 7.87 feet. The water-power concession authorized the use of 424 cubic feet per second during dry periods and 636 cubic feet under normal conditions, that is 384 to 576 theoretical horse-power, according to the season. During the dry season, the head is at its maximum, which compensates in a certain measure for the diminution of volume. As shown in the accompanying illustrations, it was possible to establish the hydraulic plant against the dike built for the lock. It was not feasible to take all the water from the water-way to the lock, however, as too strong a current might be created for the management of boats, nor was there sufficient space for the construction of an independent intake between the river and the dike. It thus became necessary to provide two intakes, one from the lock waterway, limited to 212 cubic feet, and the other by the construction of a canal parallel to the dike and large enough to take the surplus water.

The power house is a small building, consisting of a generator room 35.4x42 feet in plan, with its floor 10.1 feet above the normal level of the head waters, and of two water chambers underneath, one corresponding to each waterway. In the floor of each chamber, at tail water level, is placed a vertical turbine, the two of equal power. To compensate for the difference of delivery in the two waterways of approach, a gate is provided between chambers to bring the two into communication, which allows each to receive the same quantity of water. In order not to hinder the service of navigation by too sudden variations of water level, resulting from stoppage or starting of the turbines, each chamber is provided, as shown in the cross-section of the plant, with a cylindrical bypass gate, the discharge of which is equal to that of the turbine. The gate is operated in conjunction with that of the turbine, in such a way that when the turbine gate is open, the bypass gate is closed and vice versa, and such that the discharge is practically constant whatever the degree of opening. Because of variations in the level of tail water the turbines are frequently under water and the so-called American type of turbine was chosen. They were built by Messrs. Teisset, Veuve Brault & Chapron, of Chartres. They have a rating of 200 horse-power each, under a head of 7.55 feet, and their speed is 41 turns per minute between the limits of 7.55 and 4.59 feet.



Water-Power Plant at Fumay, France.

Each of the wheels drives a pair of bevel gears which turn a horizontal shaft at 143 revolutions per minute, and from that by means of a belt the electric generators at 400 revolutions. The two horizontal shafts may be coupled together and each pinion and the pulley it commands can be disconnected from the turbine which ordinarily drives it, so that either one of the alternators can be driven from either one of the turbines, in case diagonally opposite machines should be for the time being out of use, and one alternator can be operated from two turbines, an arrangement which is advantageous when the head is reduced from high water and each turbine, for example, is only producing one-half of its power; the efficiency of a generator operating at full load is evidently better than that of two generators operating at half load.

The alternators, each of which carries its exciter on an extension of the shaft, furnishes three-phase current at 3,500 volts and a frequency of 40 periods per second. The current is carried in three copper wires a distance of about 5,250 feet, passing underground at a railroad bridge, crossing the dike at 59-feet above ground on wooden bents and through a built-up section with an insulated covering on the roofs of the houses. The high-tension line ends at two transformers, each of half the total power, in the central station of the works. The low-pressure winding of the transformers is of the star type, 115 volts per phase, allowing for 200 volts for general power work and 115 volts for lighting. The current from each transformer as well as from the steam driven generator is controlled from a switchboard in the central station.

For the steam unit, a Delaunay-Belleville high-speed vertical engine was adopted. It is double tandem compound machine rated at 220 horse-power at 400 turns per minute, and is provided with a jet condenser. The generator is directly connected to the engine and furnishes three-phase current, likewise at 200 and 115 volts. In connection with this generating set, a Belleville boiler, capable of generating 6,600 pounds of dry steam per hour at a pressure of 213 pounds per square inch, has been installed. From the boiler steam passes into an expansion chamber, which brings it to 127.8 pounds per square inch, then into a steam separator at the engine. Throughout the works there are about 30 motors taking an average of 150 horse-power and 900 incandescent lamps of 16 candle-power taking 60 horse-power; in addition electrical heating apparatus requires 5 horse-power. The works are described in a recent issue of "Le Genie Civil."

Lowering a Heavy Foundation Girder.

The large steel-cage twenty-story office building now being erected at the corner of William and Pine Streets, New York, has a grillage foundation to which the column loads are transmitted through unusually heavy distribution girders. Four of them, with triple solid-plate webs, are 38 feet long, 5½ feet deep and 32 inches wide over all and weigh about 30 tons each. They were brought to the site on special trucks drawn by eighteen horses and were unloaded by hydraulic jacks on cribbing in the street close to the edge of the cellar excavation. After the truck had been released, the girder was jacked down to skids at the street level. The skids reached to the edge of the excavation where they met the tops of four 12x12-inch timbers inclined about 30 degrees to the horizontal and supported at the bottom on the cellar floor, at the top on the tops of the sheet piles enclosing the excavation, and intermediately by 12x 12-inch caps of two transverse trestle bents which were X-braced in longitudinal and transverse vertical planes. Both inclined timbers and horizontal skids had loose flat steel bearing strips on top which were greased for the girder to slide upon.

The girders were unloaded with their webs in horizontal planes and the edges of their flanges bearing on the greased track plates on the horizontal skids. A heavy chain sling was passed around each end of the girder and another near the middle, with the rings on the side farthest from the excavation. The hoisting tackle from the boom of a large guyed derrick seated in the excavation was attached to the middle sling. To each of the other slings there was attached a six-part manila tackle, which was shackled to a chain around a parallel duplicate girder laid flatways on the curb to act as an anchor. A third tackle was attached to one of the end slings and was anchored through a coal hole in the sidewalk on the opposite side of the street.

The girder was jacked over to the top of the inclined skids, the opposite edge jacked up, and then started sliding down, being held back by the three preventer tackles and by the boom tackle which overhung the edge of the excavation and was operated by the hoisting engine. The lead lines from the other tackles were snubbed with several half turns around the shackles or links of the chains on the anchor girder, and three men on each paid them out as the girder descended. The girder was lowered smoothly and rapidly and reached the cellar bottom, about 18 feet below the street, in five minutes after it commenced to descend. It was landed on the greased flanges of I-beam skids and was turned 90 degrees and slid into place. About twenty men in all were required to handle and unload the girder. Mr. James B. Baker is the architect of the building, and the contractors are the Thompson Starrett Company, Mr. S. C. Weiskopf, engineer. The girders were built at the Pencoyd shops of the American Bridge Company.

The four-wheel truck on which the girders were brought to the site imposed so heavy a load on the pavement that near where the girders were unloaded one wheel broke through the pavement and the arched roof of the sidewalk vault, and made a large hole there. Another girder was delivered in the daytime and when the truck turned down Broadway to Wall Street it was necessary to unhitch the eighteen horses to turn the corner and hitch them on again in Wall Street. This carried the line of teams across both tracks of the Broadway electric cars and shut off all traffic so long that the street was blocked for many squares and more than fifty cars were stalled there.

This method of lowering a heavy weight on inclined skids elicited a description of some similar work done by the T. A. Gillespie Company in the construction of the pipe line of the Utica Electric Light & Power Company. A 7-foot steel pipe carries the water from the dam across the west branch of Canada Creek to the bottom of a very steep hill over 150 below, and there has a T and four 6-foot gate valves, the latter weighing 12 tons each. The T has three 7-foot openings and weighs 46,000 pounds. It was unloaded from the cars about a mile from the top of the hill and was transported there on a platform built on two low four-wheel car-trucks, which were moved over the rough ground on a narrow gauge track consisting of two sections of rails fastened together with bridles. The section in the rear of the trucks would be disconnected, taken up and brought around and connected on in advance, the trucks moved one length ahead, the other section of track moved around in front and so on. The road was fortunately down-hill and the trucks moved easily and had to held back by preventer tackles.

The pipe trench had been dug from the foot of the dam to the bottom of the hill and in it skid rails were laid at an angle of about 15 degrees with the vertical and the 23-ton casting was slid down on them. It was lowered with two preventer tackles and the hoisting tackle of a guyed derrick on top of the hill. The derrick had a mast 24 inches in diameter and a 60-foot boom 20 inches in diameter, and was rigged with ¾-inch steel plough rope and six very flat guy lines. Before lifting the T, the derrick was tested with one of the 12-ton gate valves, which it lifted over a large sand pile, with its boom in a flat position; the line was then slacked off a few inches and suddenly stopped so as to cause a very heavy impact, which, however, did no injury.

METHOD OF LOWERING A HEAVY FOUNDATION GIRDER.

It required about 15 minutes to lower the T down the skids, two men riding down on it with bars ready to free it from any obstruction.

The pipe line was 4,000 feet long and included 3,000 feet of 7-foot wood stave pipe and 1,000 feet of 7-foot riveted steel pipe up to ⅝-inch thick, which was delivered in sections 30 feet long and riveted and calked with pneumatic tools. It had a 7-foot riveted steel standpipe 180 feet high, the lower 60 feet of which was assembled and riveted together horizontally on the ground. The special connection to the horizontal line was riveted into it, and the pipe was lifted bodily by tackles suspended from large trees which were utilized for derricks and revolved into a vertical position. It was then guyed and completed by building on the upper part with inside and outside scaffolds and a light inside revolving T-derrick which carried the yoke riveting machine and hoisted the plates.

The Mechanical Plant in a Newark, N. J., Department Store.

A new building containing an interesting mechanical plant was completed early in the year for the department store of Hahne Brothers, of Newark, N. J. A complete steam plant was installed for the warming of the building and to operate four electric generating sets, several pumps and other steam apparatus. On the lighting circuits there are 12,000 incandescent lamps, and 550 enclosed arc lights. A fire sprinkler system is provided, an ice plant furnishes refrigeration for a restaurant, a grocery and ice cream boxes, for cold drinking water, for a soda-water establishment and for a fur storage room. The mechanical equipment includes 15 electric sewing machines, two electric package carriers, a merry-go-round and two exhausters for a cash carrier system. The plant is located in the basement and occupies a wing of the building, one end being separated from the remainder of this floor by a glass partition affording a view of the machinery to visitors.

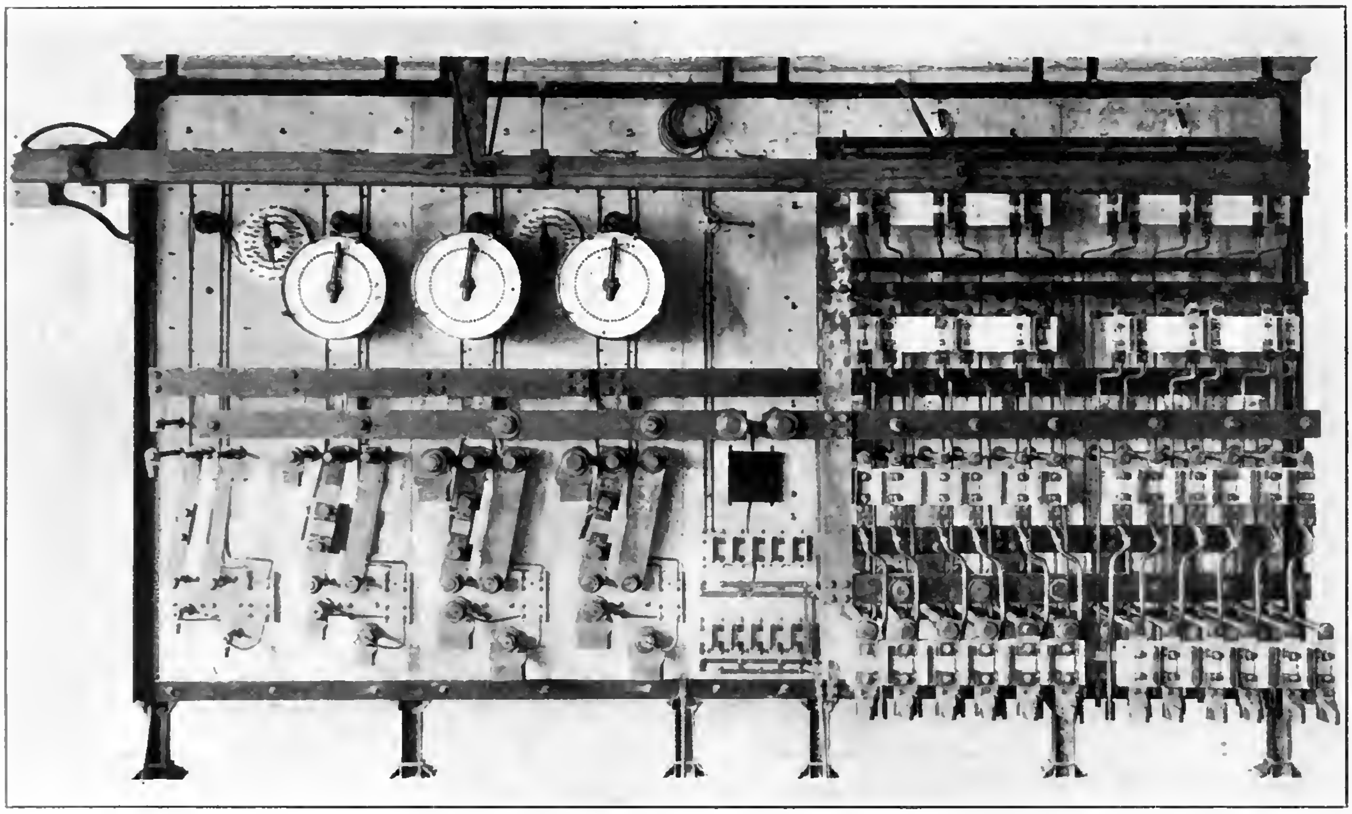
The main entrance to the building is on Broad Street, where there is a frontage of 240 feet, and the building extends along Neu Street for 255 feet to Halsey Street, there having a 100-foot front. This rear wing of the building is 140x100 feet in plan, where, in the basement, the mechanical plant is situated. The main body of the structure is lighted by two wells or rotundas located on each side of the center and extending to the roof. It is four stories high, exclusive of the basement.

The steam plant includes four Cahall water-tube boilers, each of 250 horse-power, and arranged in two batteries of two boilers apiece. They are individually connected to a four-piece steel smoke breeching 5 feet in diameter, which runs in front of the boilers overhead to a steel smokestack 6 feet in diameter and 100 feet high. Coal is taken from a vault of 90 tons capacity at the rear of the boilers and carried on a trolley to the firing pits. The fire boxes are fitted with Adams shaking grates. From each of two steam drums on each boiler, which are 20 feet long by 3 feet in diameter, a 3-inch connection joins a 5-inch supply pipe. The latter in each instance is run to a 12-inch header. Brick settings support the boilers, with suitable provision for expansion and contraction of the shells.

In a pit nearby are situated the boiler-feed pumps, two in number, one of which is 7x4½x8 inches in size and the other, 10x6x10 inches. They are of the Worthington type, and are piped so as to take the returns from the heating system, as well as fresh water from the city mains and deliver to the boilers through a 1,000-horse-power Berryman feed water heater, located on the opposite side of the stack. The pumps operate in connection with a governor in the usual way. Two smaller pumps are situated in the same pit; one pump takes care of and empties into a receiver shown; the other is used to empty a sump and discharges into the same tank. A boiler blow-off tank is combined also in the latter.

Steam from the 12-inch header mentioned is conveyed by branch lines of several sizes to the generating sets, four in all. Two of them are of 200 kilowatts capacity, a third is a 100-kilowatt set and the fourth has a 50 kilowatt capacity. The large sets in each case consist of a 21x18-inch, horizontal high-speed engines of the piston valve, side crank type, manufactured by the Harrisburg Foundry & Machine Works, of Harrisburg, Pa., and a 120-volt direct-connected multipolar Crocker-Wheeler generator. One of the other two dynamos is also a Crocker-Wheeler direct coupled to a 16x16-inch Harrisburg engine of similar construction, with a speed of 250 revolutions under 125 pounds steam pressure per square inch. The fourth set is composed of a 50-kilowatt Siemens & Halske generator, driven by a 12x12-inch engine, made by the Ames Iron Works, of Oswego, N. Y.

These dynamos furnish current to a two-wire lighting and power system combined. The arc lights are operated on the same voltage as the incandescent lights, namely, 110 volts. They are of the Manhattan 1,200-candle-power enclosed type. On the first floor there are 18 points of distribution and nine risers lead upward to the floors above. A separate riser is provided for a sign directly over one of the wells on the roof and another is run to the soda water fountain on the second floor, there supplying a number of arc lights under a stained glass dome. From four to five incandescent lights are provided for each show case and incandescent lights are also placed installed on floor columns. In the latter instance brackets are introduced and clusters of lamps attached. The aisles in the building are lighted by the arc lamps, while the courts in the interior of the structure are illuminated by a bank of incandescent lamps at each story. On the Broad street and New street fronts the show windows are supplied with numerous incandescent lights, with Frink reflectors, placed at a distance of from 8 to 10 feet apart, and on the Halsey street windows the same illumination is provided for a distance of 60 feet. The Broad street entrance is furnished with crystal dish lights, and in the vestibule there is also a row of 118 incandescent lamps arranged to shine through rosettes. The music hall on the second floor is supplied with about 250 amperes for incandescent lighting and a separate riser has been installed for this system.



View of the Rear of the Switchboard.

The power apparatus consists of a 5-horse-power Crocker-Wheeler motor, which is employed to run the merry-go-round, and a 10-horse-power motor of the same make for the running of an escalator, which travels from the center of the main floor near the rear court to the second floor. Power is also taken for the operation of 15 sewing machines on the fourth floor, where a small motor drives a line of shafting to which they are belted. Two package carries are also run from an electric circuit.

The switchboard, a photograph of the back of which is reproduced, consists of five panels of white Italian marble, two of which are occupied by generator accessories, a central panel by a recording wattmeter, a clock and several switches, and the remaining pair of panels by the main distributing switches. Circuit breakers of the I. T. E. type manufactured by the Cutter Company, of Philadelphia, two of them being of 1,600 amperes capacity for the large machines, and 800-amperes for the 100-kilowatt generator and one of 400 amperes for the Siemens & Halske generator, are contained on the board. Four pilot lamps, four Weston ammeters and two Weston voltmeters are provided for the generator panels. The rear of the switchboard shows the positive and negative bus-bars, the reverse side of four rheostats and the arrangement of all switches. It will be noted that fuses are inserted in the feeder circuits mounted on panels on the rear of the board and that all cables are connected to the switchboard connections at the floor.

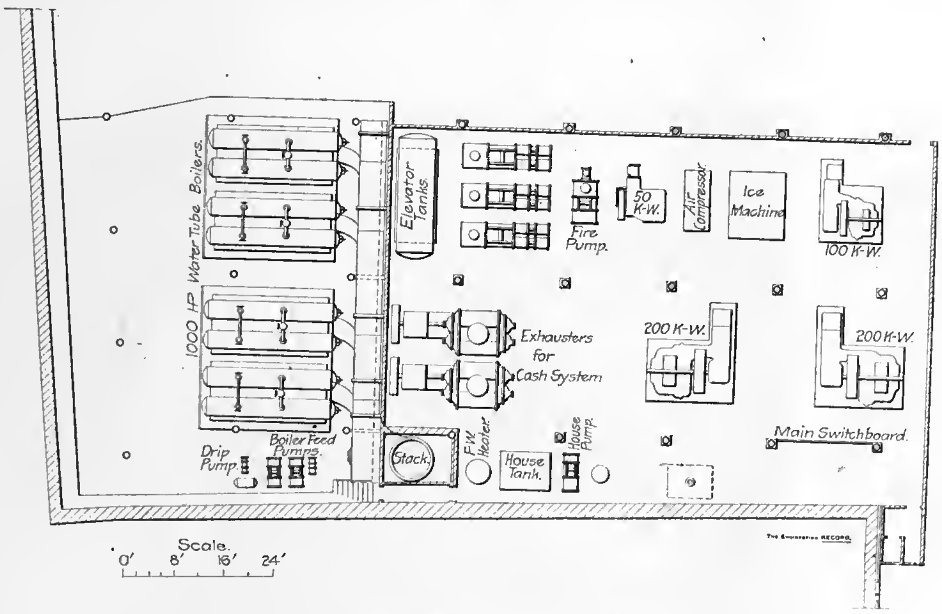
There are 13 hydraulic elevators in the building, which were furnished by the Plunger Elevator Company, of Worcester, Mass. Three compound Deane pumps, each 14x20x18 inches in size, a surge tank, and a pressure tank are installed in the engine room. The pumps receive water from the surge tank 6½ feet in diameter and 13 feet long, and discharge into a pressure tank, 18 feet long and 6 feet in diameter suspended above the former, by straps and wrought iron hangers; a pressure of about 150 pounds per square inch is maintained. The elevators travel at the rate of 400 feet per minute through a total lift of 60 feet, and have a carrying capacity of about two tons.

A complete fire system has been installed in the store, which comprises a sprinkler arrangement and the usual pumping outfit. In both cases artesian well water is used which is raised to the surface and discharged into a cistern beneath the basement floor by a Blake air compressor 10x12x12 inches in size. From this cistern the water is pumped to three tanks on the roof, each of which is capable of holding about 20,000 gallons. The pump in use for the latter purpose is 18x10x12 inches in size and was furnished by the Snow Steam Pump Works, of Buffalo, N. Y. A standpipe connects the tanks with the supply pipes of the sprinkler system, which was supplied by the General Fire Extinguisher Company, of New York. An additional fire underwriters' pump, located in the basement, connects with fire apparatus throughout the building.

Artesian well water is also used in the refrigerating plant for condensing purposes. This plant operates on the ammonia compression system, and a compressor made by the Remington Machine Works, of Wilmington, Del., is installed. A submerged condenser is used and one ton of ice is made per day. The various departments in which refrigeration is required have already been enumerated, the drinking water being circulated by a 1¾x2½x5-inch pump supplied by the same company and located near the other apparatus. The fur storage room is kept at a temperature of 25 degrees Fahrenheit, the ice boxes at 30 degrees and the drinking water at 45 degrees.

In addition to the general apparatus mentioned there is a cash carrier system and two Wilbraham Baker Blower Company's exhausters driven by vertical engines produce a suction in the carrier tubing to which they are connected of about 2 pounds below atmospheric pressure. A two-pipe steam heating layout serving about 10,000 square feet of direct radiation, warms the building in the winter months, and throughout the building Johnson thermostats are used for temperature regulation. Steam piping in all cases is insulated with magnesia covering made by the H. W. Johns-Manville Company, of New York.

The architect for the store was Mr. Goldwin Starrett, of the Thompson Starrett Company of New York. The mechanical plant was designed by Messrs. Osterberg & Sutton, of New York, and the electrical plant by Mr. H. D. Babbitt, of the Thompson Starrett Company, which was the contractor for the engines, dynamos, switchboard and electrical apparatus. Mr. Benjamin F. Pangborn is the chief engineer for Messrs. Hahne Brothers.



Plan of the Mechanical Plant.

A Complication of Water Rights.

In 1852, the first settlement of Herriman, Utah, was made at a place where a small stream, Butterfield Creek, afforded water for irrigation and domestic purposes. Later the water users incorporated the Herriman Irrigation Company to control the use and distribution of the water, all of which had been appropriated by them. The entire flow of the stream was thus used until 1894, when George W. Keel and his associates put in a headgate on the creek about two miles above the company's point of diversion, and diverted about half the water then passing down the channel. This appropriation has continued to the present time and has been the cause of prolonged litigation, which is of interest to all hydraulic engineers and managers of water-works. The appropriation of half the flow of the creek was based on the fact that Keel and other defendants in the suits had, prior to the diversion of any water by them, driven two mining tunnels on their own land, the Queen tunnel, about 2,900 feet long, and the Butterfield tunnel, about 8,200 feet. A large amount of water was encountered in these tunnels and allowed to flow into the creek, and it was only this water that the defendants appropriated, according to their claims. The company claimed that the water developed by the tunnels came from the sources feeding springs which yielded part of the flow in the creek, and that these springs had been dried up by the tunnels. On the other hand the owners of the tunnels pointed to various springs still flowing in the vicinity of those said to have existed prior to the driving of the tunnels, and asserted that if any springs had ceased to flow the cause was to be sought in the reduced annual rainfall and the destruction of forests. The evidence was held by the courts to show that the water comes from the Butterfield tunnel 5,500 feet and farther from its portal, and that there was no indication of any channel between the tunnel and the springs said to have been affected by it, one to one and a half miles distant. Such a state of affairs has all the elements of vigorous controversy as to both facts and law, and it is not surprising that it has produced prolonged litigation. The latest decision of the Utah Supreme Court, 90 Pac. Rep., 719, contains references to a number of legal points not particularly interesting to engineers, and these are omitted in the following condensation of the opinion, which was written by Judge Bartch.

The first technical point to be settled by the court of appeals was a question of fact, whether or not the tunnels caused the drying of springs that fed the creek. Judge Bartch was unable to find any proof to support a claim that the tunnel had such an effect. It was shown that the springs, which, it is claimed, have ceased to flow, are from a mile to a mile and a half from the tunnels. Butterfield canyon extends in a direction substantially east and west, and the tunnels are located on the north side of the canyon and extend into the mountain on that side. The timber and undergrowth which formerly retarded the melting of the snow and retained the moisture have been removed and destroyed. The country in that vicinity appears to be stratified, and there is evidence tending to show that the dip of the stratification is towards the north, and that consequently, on the north side of Butterfield canyon, the waters sink into the soil and rocks, and are carried by the stratification along the bedding planes in the opposite direction from Butterfield creek. Messrs. C. L. Stevenson and A. F. Doremus, after explaining the topography of the country in question, each testified in the trial court that in his opinion, after an examination of that section of country lasting for a period of 10 days, the springs were not affected by either tunnel, Mr. Stevenson stating that it was a physical impossibility for the springs to be dried by the tunnels. Mr. Doremus also stated that he "saw nothing to indicate springs had dried." Other testimony of like nature was presented, and the trial judge visited the tunnel and site where the springs were said to have existed and came away convinced that the opinions of Messrs. Stevenson and Doremus were correct. Hence, although conflicting testimony was given by the company's witnesses, Judge Bartch held that the trial court was justified in holding that the tunneling operations had not affected the springs.

If, however, notwithstanding the evidence in support of the finding, it were admitted that it was unwarranted, still such admission could not avail the appellant, the irrigation company, as will be observed upon further consideration of the facts and of the law applicable to them. This is so because the trial court further found: "That the waters that came into said tunnels during the prosecution of the work therein, and that have since and that now come into them, are waters percolating from the surface into the rocks, and through the cracks, fissures, and seams in said rocks, till they find an outlet into the tunnels through innumerable small spaces, through which the waters flow and drip into said tunnels. At no time before or during the making of said tunnels, or since, did any of the waters coming into said tunnels flow underground in streams that were known to exist, or that could be discovered, or that had well-defined channels with beds and banks; but said waters, before the making of said tunnels, were caused by rains or melting snows entering the surface of the ground and percolating through the rocks, where they either remained stationary, or moved in the rocks through the small cracks, fissures, and seams therein, and in courses and directions unknown and that were not then and are not now visible to observation; and their existence and course is only a matter of theory and speculation."

The evidence absolutely fails to show that any known and well-defined subterranean streams connected the springs with either of the tunnels. There is no evidence whatever showing that any one, before the driving of the tunnels, knew how the water existed in that mountain—whether it was percolating through soil and rocks, running in streams, or was motionless. There were no surface indications of channels or streams, or of any body of water, where the tunnels were located. Not until the tunnels cut the water-bearing strata did any person, so far as shown in the evidence, pretend to know that the water existed there in streams, and that those streams supplied springs a mile and a half distant. Nor were the tunnels driven for the purpose of developing a stream of water, or with any malice toward the appropriators of the surface stream. They were driven as a mining venture in the hope of finding ore. This was a legitimate enterprise, in which the owner of the land had the right to engage, and the water which he found, in digging the tunnels, where no known or defined streams existed, belongs to him as much as does the land itself; and this, even if thus, unexpectedly, in the nature of things, he gains an advantage over his neighbor. Such water, so hidden in the bowels of the earth, belongs to the owner of the soil, and he has the right to dig for it upon his own land and appropriate it and use it if he chooses to do so; and if thereby a loss results to his neighbor, it is damnum absque injuria.

Such right exists in the owner because, by the general consent of mankind, which is inferred from the very nature of the right, every owner of land is entitled to the natural advantages belonging to it. Water standing in the land underneath the surface, or passing through it, or into it, by filtration, percolation, chemical attraction, or in undefined and unknown streams, is such an advantage, which the owner of the land is left to enjoy. The law of surface streams does not apply to such water. If it were otherwise, no man would be safe in operating a mine, or even in digging a well, upon his land, for, by so doing, he might interfere with percolation, or cut an undefined stream hidden from observation, and thereby diminish or stop the flow of his neighbor's spring, and render himself liable in damages, however innocently the work might have been performed. The sequence would be the hindrance or prevention of improvements and progress. Where streams of water appear upon the surface, or in well-defined and known subsurface channels having beds and banks, there the owners of the soil over or through which they pass are bound to take notice of the rights of all others to the water; but, as to water of the nature of that developed by the tunnels in question in this case, the law is well settled that it belongs to the owner of the land; and where, as here, springs appear to exist, which flow into a surface stream, and they are not shown to be supplied by known or defined streams, the presumption is that they are formed by ordinary percolation. Such appears to be the settled law both in England and in this country.

In Cooley, Torts (2d Ed.) pp. 689, 690, the author says: "If one by an excavation on his own land draws off the subterranean waters from the land of his neighbor to the prejudice of the latter, no action will lie for the consequent damage. This is fully settled in England by the leading case of Acton v. Blundell, 12 Mees. & W. 324, and in a later case it is decided that prescriptive rights cannot be gained, in subterraneous waters, which will preclude such excavations on adjoining grounds as may draw them off. These decisions have been generally followed in this country, and it may be considered settled law that, if the well dug by one man ruins the well or spring of his neighbor by drawing off its water, it is damnum absque injuria. Probably, if the subterraneous water were a stream flowing in a well-known course it would be different, and one through whose land it flowed would be protected against its being drawn away from him. But one claiming rights in such a stream would be under the necessity of proving its existence and tracing it—not an easy task in any case."

So, in Gould, Waters, Sec. 280, it is said: "Water percolating through the ground beneath the surface, either without a definite channel or in courses which are unknown and unascertainable, belongs to the realty in which it is found. The rule that a man may freely and absolutely use his property so long as he does not directly invade that of his neighbor, or consequently injure his clearly defined rights, is applicable to the interruption of subsurface supplies of water or of a stream; and the damage resulting therefrom is not the subject of legal redress. The landowner may, therefore, make a ditch to drain his land, or dig a well thereon, or open and work a quarry upon it, or otherwise change its natural condition, although by so doing he interrupts the underground sources of a spring or well on his neighbor's land." In Kin. Irr., Sec. 49, the author says: "Percolating waters are those which pass through the ground beneath the surface without definite channels, although the same rules of law govern those which have definite channels but the course of which is unknown and unascertainable. Where there is nothing to show that the waters of a spring or well are supplied by any defined flowing stream, the presumption will be that they have their source in the ordinary percolations of water through the soil. Percolating waters, and those whose sources are unknown, belong to the realty in which it is found."

The Utah Supreme Court, in Crescent Min. Co. v. Silver King Min. Co., 54 Pac. 244, where water was developed by driving a tunnel for mining purposes, and after flowing from the tunnel was claimed by the plaintiff, said: "The waters issuing from the artificial tunnel into the lake are found to be underground, percolating waters from the mining claim of the defendant, and not waters naturally flowing in a stream with a well-defined channel, banks, and course. Under such a state of facts, the law seems to be well settled that water percolating through the soil is not, and cannot be, distinguished from the soil itself. The owner of the soil is entitled to the waters percolating through it, and such water is not subject to appropriation. The ordinary rules of law applying to the appropriation of surface streams do not apply to percolating and subterranean streams with undefined and unknown courses and banks." So, in Irrigation Co. v. Michaelson, 60 Pac. 943, it was said: "Water commingling with the ground or flowing through it by filtration or percolation, or by chemical attraction, is but a component part of the earth, and has no characteristic of ownership distinct from the land itself. In the eye of the law, water so commingled and flowing, or motionless, underneath the surface, is not the subject of ownership apart and distinct from the soil. If, however, subsurface streams of water flow in clearly defined channels, it is otherwise; for then the rules of law applicable to surface streams and waters apply."

The Supreme Court of Pennsylvania, in Haldeman v. Bruckhardt, 45 Pa. 514, says: "A surface stream cannot be diverted without knowledge that the diversion will affect a lower proprietor. Not so with an unknown subterraneous percolation or stream. One can hardly have rights upon another's land which are imperceptible—of which neither himself nor that other can have any knowledge. No such right can be supposed to have been taken into consideration when either the upper or lower tract was purchased. The purchaser of lands on which there are unknown subsurface currents must buy in ignorance of any obstacle to the full enjoyment of his purchase indefinitely downwards, and the purchaser of lands on which a spring rises, ignorant whence and how the water comes, cannot bargain for any right to a secret flow of water in another's land. It would seem, therefore, most unreasonable that the latter should have a right to prevent his neighbor from enjoying his own land in the ordinary way either by digging wells, cellars, drains, or by quarrying and mining." Then, after reviewing authorities, the court further says: "There are known streams to which, if the lower proprietor has any rights, they are perceptible, and require no subsurface exploration before their course can be defined. We are not, however, to be understood as intimating that an owner may maliciously or negligently divert even an unknown subterranean stream to the damage of a lower proprietor. But in the enjoyment of his land he may cut drains or mine or quarry, though in so doing he interfere with the flowage of water in hidden, unknown, underground channels."

In Frazier v. Brown, 12 Ohio St. 294, it was observed: "The law cannot properly limit the ordinarily absolute dominion of the owner of the soil, in respect to things concealed and hidden in the bowels of the earth, nor recognize an adjoining proprietor as having claims upon, or rights in, a thing passing under the surface of his neighbor's land, the existence of which was first revealed by the very act which would constitute the subject-matter of his complaint."

So, in Ocean Grove Camp Meeting Ass'n v. Asbury Park Com'rs, 3 Atl. 168, it was said: "The courts all proceed upon the ground that waters thus used and diverted are waters which percolate through the earth, and are not distinguished by any certain and well-defined stream, and, consequently, are the absolute property of the owner of the fee as completely as are the ground, stones, minerals, or other matter, to any depth whatever beneath the surface. The one is just as much the subject of use, sale, or diversion as the other."

The irrigation company further contended that the respondents abandoned the water flowing from the tunnels, by turning or permitting it to flow into Butterfield creek, and that, therefore, it was subject to appropriation the same as unappropriated water of a surface stream. On this point, the trial court found that "in turning the waters of the Queen and Butterfield tunnels into Butterfield creek, the Butterfield Mining Company did not intend to abandon the same or the use thereof, but intended to take the waters from the creek at some point further down, and to apply and use the same, before reaching the creek, for the purpose of milling its ores, when needed for that purpose." Counsel for the appellant insisted that the evidence is insufficient to support this finding, but, from an examination of the testimony, Judge Bartch held the finding was justified. It is evident that there was no intention on the part of the owners to abandon the water, and no adverse title had been acquired under the statute of limitations or by prescription. The owners of the land were also the owners of the water, and they had the right to use it or dispose of it in any legitimate way they saw fit. For the purpose of applying it to some proper use, the owners had, under the circumstances appearing in evidence, the right to turn it into the natural channel of Butterfield creek, and, after permitting it to flow therein for some distance, had the right to divert it again from such channel, if by so doing they did not divert more water, after making due allowance for evaporation and seepage, then belonged to them and did not interfere with any rights of prior appropriators of the waters naturally flowing in the said channel.

There appears to be nothing in the record which would warrant the position that the respondents were diverting more water than belonged to them, or that they unlawfully interfered with the rights of any prior appropriator. The mere turning of the water in the natural stream was not an abandonment of it, nor did such act prevent the owner from again claiming it. The burden, however, is upon him who turns water into a natural stream to show that he has not taken more out of it than belonged to him. This, according to the findings, was shown.

This opinion is concurred in by the other judges, except in one particular, but that is the important one as to the effect of the tunnels on the springs which formerly supplied water to the creek. In this respect the majority of the judges overrule the findings of the trial court and the opinion of Judge Bartch. They hold that while considerable water flows in the tunnels which has no appreciable connection with any surface supply, nevertheless some of the tunnel water comes from sources which formerly supplied springs now entirely dry or of greatly diminished volume. In view of the testimony by Prof. James E. Talmage, Mr. E. S. Hinckley and other geological and engineering witnesses for the irrigating company, the majority opinion of the court is that the mining interests are entitled to take from the creek only one-half the water entering it from the tunnels less 8 per cent. allowance for evaporation and seepage. The other half of the discharge from the tunnels is held to be water which would have reached the creek had the tunnels not been driven. The case was accordingly remanded to the lower court to be decided on these lines, the costs to be equally divided between the two parties.

Trade Publications.

The electrical supplies now handled by the H. W. Johns-Manville Co., New York, are so varied that the new catalogue covering them is a book of over 100 pages. It describes various insulating devices for line work, car fittings and dynamos and motors; switches, fuses and cut-out equipments; car heaters, insulated tools and insulating materials, all carefully indexed.

A new catalogue of pressure and volume blowers has been issued in attractive form by the American Blower Co., Detroit. Fans of many types and sizes are described, and there are useful tables of the loss in pressure in pipes, the relative capacity of ducts of different sizes and the weights of materials used in ducts.

Bucket elevators for lifting water are described in a folder from the Jeffrey Mfg. Co., Columbus, O. They are used in wells, for drawing water from streams for irrigating, and in other situations where horses are available for operating the lifts.

Two forms of pile drivers mounted on a turntable on a heavy flat-car are described in a special catalogue issued by the Vulcan Iron Works, Chicago. One of the cars is self-propelling and the other is not; both can be used with either a drop or a steam hammer. A lighter wooden driver mounted on a car, but not revolving on a turntable is described, and various sundries are illustrated.

An album of views taken along the New York subway has been prepared by the Carson Trench Machine Co., Boston. Twenty-two Carson-Lidgerwood cableways are used on the work for excavating and handling materials, and the illustrations show forcibly how little obstruction these plants offered to the traffic on the streets.

The Copper Cliff Mining Co., 79 Dearborn Bldg., Chicago, has prepared a well-illustrated description of the process and plant employed in making "CC" graphite paint. Starting with a naturally silicated graphite and linseed oil, the company makes a product for boiler fronts, steel stacks, steelwork in bridges and buildings, piping in refrigerating plants and other situations where the conditions are particularly trying.

Two new bulletins of the Fort Wayne Electric Works are No. 1,026 on enclosed direct-current series arc lamps, and No. 1,033 on integrating switchboard ammeters for single-phase currents. They give fully illustrated descriptions of the details of the devices mentioned.

The patents on the Kansas City wheeled scraper were purchased some time ago by the Smith & Sons Mfg. Co., Kansas City, Mo., which has used those of proved value, along with many new improvements, in the design of the Royal scraper which it has lately placed on the market. This is made in three sizes fully described in an elaborate catalogue just issued, together with drag scrapers and contractors' plows.

The recent publications of the General Electric Co., Schenectady, N. Y., include the following new bulletins: No. 4287, single-phase alternating-current 125-cycle generators; No. 4290, electric railway apparatus; No. 4291, compensated revolving field alternators; No. 4292, CE generators; No. 4293, constant-current transformer panels; No. 4294, the GE-73 railway motor. In addition to these bulletins the company has issued a pamphlet on the advantages of using oil in transformers; a beautifully illustrated description of lightning arresters, with an introductory chapter by Prof. Elihu Thomson on atmospheric electricity and lightning protection, which has engravings from a number of photographs of lightning flashes; and a large book describing all types of pumping machinery which have been driven by General Electric motors.

The U. S. Electro-Galvanizing Co., 346 Broadway, New York, describes in a new pamphlet the advantages of a system of cold galvanizing which it controls. A number of letters from licensees are given, some containing reports of interesting tests of the system.

A ventilator or cowl for discharging air from buildings is well illustrated in a brochure prepared by the Buffalo Forge Co., Buffalo, N. Y. This is so designed that a wind from any direction will draw air from the building.

The advantages of warm water and steam heating systems are outlined with unusual clearness in a little pamphlet from the Herendeen Mfg. Co., Geneva, N. Y. The discussion is wholly untechnical and written for the general public, yet it presents the merits of the Furman heating apparatus in a skilful manner indicating its preparation by some well-trained writer.

A 48-page list of many varieties of twist drills with taper, straight and square shanks and adapted for all services between those of a jeweler and the drill-press of a machine shop, has been issued by the Standard Tool Co., Cleveland, O.

The new catalogue of steam specialties made by the Lunkenheimer Co., Cincinnati, is a book of 208 pages profusely illustrated and well indexed. The list embraces brass and iron valves, injectors, whistles, lubricators, oil and grease cups, and steam specialties, and the book is so comprehensive and clearly written as to be invaluable to designers and owners of any class of steam plant.

Personal and Obituary Notes.

Mr. John M. Bruce has resigned as secretary of the Engineering Review Co., to become treasurer of the Judson A. Goodrich Co., New York City.

Mr. Alexander J. Taylor has resigned his position as sewer engineer for the Street and Sewer Department of Wilmington, Del., to take charge of street and sewer work for Mr. T. Chalkley Hatton. Mr. Francis R. Price, third assistant in the city surveying department, has been appointed his successor.

Edmund Phillips Hannaford, M. Am. Soc. C. E., died suddenly at his home in Montreal, P. Q., August 18. He was born in Devonshire, Eng., in 1834, and entered railway service in 1851 as draftsman. Until 1855 was a member of the engineering corps of the South Devon Railway and in the following year came to Canada. From 1857 to 1866 he was assistant engineer of the Grand Trunk Railway and was then appointed chief engineer of the Western Division. In 1869 he became chief engineer of the company and resigned from active work in 1896. Many new lines were constructed during this period of perhaps the railway's greatest development. In 1869 he was appointed chief engineer of the International Bridge.

Augustus Torrey, chief engineer of the Michigan Central Railroad, died in Detroit, August 20, from the results of an accident while on an inspection tour the day before. He was born in Beverly, Mass., in 1850, was graduated from the University of Vermont in 1872 and was first engaged by the Burlington & Lamoille Railroad, of which he was division engineer. He resigned in 1876 to become superintendent of the Burlington, Vt., water-works. In 1880 he joined the Michigan Central as assistant engineer and became chief engineer in 1892. During his administration he was prominently identified in matters of roadway improvement, introducing among other things a ballast-loading machine and a form of rail joint. He was the author of "Switch Layouts and Curve Easements." Mr. W. S. Kinnear, formerly superintendent of the Canadian division of the Michigan Central Railroad and latterly assistant to the general superintendent, has been appointed chief engineer, succeeding Mr. Torrey.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xviii and xxvii.

WATER.

Atlanta, Ga.—Supt. of Water Wks. Park Woodward writes that the proposition to increase the capacity of the filtration plant is under consideration, but the Council has not yet made the appropriation for said improvement.

Newmans Grove, Neb.—At the special election held Aug. 19 the proposition to issue bonds for water works carried almost unanimously. Arnold C. Koenig, C. E., Omaha, Neb., is preparing the plans.

Gentry, Ark.—This vilage has granted a franchise to P. E. Miller for water works, which are to be constructed at a probable cost of $3,500.

Port Arthur, Tex.—City Secy. Jno. Roberts writes that J. C. McDowell, of Port Arthur, has been granted a franchise for the construction of a system of water works.

Oakland, Ill.—The Council is said to have appointed a committee to secure the services of a civil engineer to make surveys for proposed water works.

New York, N. Y.—Bids will be received by Robt. Grier Monroe, Comr. Dept. of Water Supply, Gas & Electricity, until Sept. 18 for furnishing material and building an engine, coal and boiler house for high service works at Jerome Park reservoir.

Graham, Va.—Bids are wanted Sept. 17 for constructing a water works system. O. A. Metcalfe, Town Recorder.

Grinnell, Ia.—Engr. in Charge H. H. Robbins writes that the contract for constructing a dam for the Grinnell Water Co. has been awarded to Coulson & Daley, Mt. Pleasant, Ia., for $4,957.

Dickinson, N. D.—L. A. Simpson, of Dickinson, who with A. Hilliard has the contract for the construction of a system of water works, writes that bids for said work will probably be asked about Oct. 1. Probable cost, $20,000.

St. Boniface, Man.—This town is reported to have voted to raise $100,000 to install a system of water works, and $15,000 for an electric light plant.

Hannibal, Mo.—It is stated that the Hannibal Water Co. is to make extensive improvements to its pumping station.

Philadelphia, Pa.—Bids will be received by the Dept. of Pub. Wks., Bureau of Water, until Sept. 12 for 20-in. cast iron water pipe for high pressure fire service and for an engine house, traveling crane and intake pipe for high pressure fire service. Wm. C. Haddock, Dir.

Yazoo City, Miss.—Bids will be received Sept. 8 for $175,000 water works, sewer and electric light bonds. E. J. Poursine, City Clk. Kirkpatrick & Johnson, of Jackson, Miss., Engrs.

Biloxi, Miss.—Bids are wanted Sept. 9 for furnishing and laying about 7 miles of cast-iron pipe, with hydrants and valves; also for relaying about 2 miles of wrought-iron pipe. For specifications address Kirkpatrick & Johnson, Engrs., Jackson, Miss. T. J. Roseli, Chmn., Biloxi.

Millvale, Pa.—Boro. Clk. C. W. Dankmyer writes that on Aug. 17 it was voted to issue $75,000 bonds to be used in the purchase of the Bennett water works and for the payment to the Bennett Water Co. of the amount of a verdict the company received recently against the Boro.

Baldwins, L. I., N. Y.—Bids are wanted Sept. 11 (readvertisement) for furnishing, constructing and erecting a pumping plant, with all appliances complete, at the Millburn Pumping Engine House, Baldwins; also for furnishing, delivering, erecting and connecting 2 boilers at the Millburn Pumping Staton, Baldwins, as advertised in The Engineering Record.

Durant, Ind. Ter.—Burns & McDonnell, Kansas City, Mo., have been awarded the engineering work for plans, specifications and estimates for a complete system of water works for this city.

Boston, Mass.—The following bids were opened Aug. 23 at the Bureau of Yards & Docks, Navy Dept., Washington, D. C., for constructing a concrete and steel conduit and laying a 16-in. cast-iron water main at the Navy Yard, Boston: Aberthaw Const. Co., Boston, Mass., $45,039; Simpson Bros. Corporation, Boston, $43,300.

Adams, Mass.—Bids are wanted Sept. 2 for the purchase of $30,000 Adams Fire Dist. Water bonds. F. W. Spalding, Treas. Adams Fire Dist.

Findlay, O.—Bids are wanted Sept. 15 for the purchase of $150,000 water supply bonds. Frank C. Ray, City Clk.

Golden, Colo.—Bids are wanted Sept. 2 for $100,000 gravity system water bonds.

Weldon, N. C.—G. H. Coleman, of Portsmouth, Va., writes that the company which he represents proposes to construct a $35,000 water works plant at Weldon.

Colby, Wis.—City Clk. John J. Grimes writes that on Aug. 16 it was voted to construct water works and an electric light plant.

Ardmore, Ind. Ter.—City Clk. G. H. Bruce writes that a vote will probably be taken next fall on the issue of $175,000 bonds for water works.

Vernal, Utah.—S. R. Bennion, Pres. of the Ashley Valley Irrigation & Reservoir Co. recently incorporated with a capital of $50,000, writes that said company proposes to construct reservoirs, but plans and estimates have not yet been prepared.

Cleveland, O.—The contract for building a brick chimney on foundations provided by the city, at the Kirkland St. pumping station, has been awarded to U. H. Fath & Son, for $13,905.

Wilmot, S. Dak.—Town Clk. A. Minder writes that on Aug. 11 it was voted to construct water works at a cost of $8,000.

Manning, Ia.—Engr. in Charge A. Marston, of Ames, Ia., writes that the contract for constructing a water tower consisting of a steel tank about 60,000 gals. capacity, on a steel tower 100 ft. high, has been awarded to the Chicago Bridge & Iron Co., Washington Heights, Chicago, for $7,750.

Avon, N. J.—Engrs. in Charge Halsey & Logan, 164 Market St., Newark, write in regard to proposed water works and sewerage system, that an election will have to be held to authorize the issue of $70,000 bonds for said improvements, and therefore it will be at least 2 months before bids will be received for construction.

Fairmont, W. Va.—Bids are wanted Sept. 15 for improving the water works system, as advertised in The Engineering Record.

Portland, Ore.—Clinton C. Hutchinson, Pres. of the Oregon Irrigation Co., writes that it is proposed to irrigate 200,000 acres of land from Deschutes River at an estimated cost of $2,000,000.

Trenton, Mo.—City Clk. Stephen M. Hill writes that the City Council has given the Water Co. notice to furnish better water. This is all that has been done in relation to the matter up to the present time.

Chicago, Ill.—It is stated that bids are wanted Sept. 4 for water mains in a number of streets. J. A. May, Secy. Bd. of Local Improv.

Winnipeg, Man.—City Engr. H. N. Ruttan has submitted a report to the City Council recommending a plan for the improvement of the present water supply, at a cost of $12,000, which provides for the sinking of a well 15 ft. in diameter, a well 10 ft. in diameter and a drift or horizontal conduit 6½x6½ ft. for a distance of 200 ft. from well.

Dallas, Ore.—David Calbreath, of Independence, Ore., has submitted a proposition to the city officials to put in a system of water works.

Lidgerwood, N. D.—John Nuding, City Aud., writes that on Aug. 25 it was voted to issue bonds for the construction of water works.

Scotia, N. Y.—Papers of incorporation of the Scotia Water Wks. Co. have been filed with the Secy. of State. The capitalization is $10,000. The Directors are: W. H. Sanger, of New Rochelle; G. H. Russell, W. J. Hillis, of Albany, and others.

Phillipsburg, N. J.—The Lopatcong Water Co., principal office at Phillipsburg, has been incorporated, with a capital of $100,000. Incorporators: Geo. P. Elder, Wm. Prellwitz, Sylvester C. Smith, A. L. Scott, Jr., and others.

Fredericksburg, Va.—The Com. on Water has submitted to the City Council a report recommending improvements to the water works system to cost $8,000.

Havre de Grace, Md.—A. R. T. Lackle has prepared plans for a new system of water works, the supply to be brought by gravity from the hills several miles distant. The proposition to issue $60,000 bonds for said work will probably be voted upon at a special election.

Rockville, Md.—At a recent citizens' meeting the Town Council was authorized to borrow money sufficient to install new pumping machinery for the water works.

El Paso, Tex.—Local press reports state that the City Council has decided to ask for bids for a city water plant to be located on the mesa.

Colorado City, Colo.—Taxpayers and property owners in this city are said to be agitating the building of a municipal water plant.

Norwich, Conn.—The Bd. of Water Comrs. has engaged Chandler & Palmer to secure measurements, etc., regarding proposed changes at Fairview reservoir.

Covington, Tenn.—The Bd. of Aldermen has employed J. A. Omberg, Jr., of Memphis, to draw up plans and specifications for a water works plant to cost about $17,000.

Weiser, Idaho.—At the recent election it was voted to bond the irrigation district for $60,000 for the purchase and repairing and enlarging of Galloway ditch.

Spanish Fork, Utah.—The City Council has made an appropriation for the preparation of plans for a pure water supply for the city.

Wonewoc, Wis.—Bids will be received until Sept. 8 by the Village Clk. for furnishing and laying 7,781 ft. of 4, 6 and 8-in. cast iron pipe, 17 hydrants, 2 8-in., 3 6-in. and 1 4-in. valves and boxes, 5,910 lbs. of special castings, and 1 50,000-gal. concrete reservoir. W. G. Kirchoffer, Engr., Baraboo, Wis.

South Atlantic, N. J.—Bids will be received by the City Clk. until Sept. 15 for furnishing material and completing a water works system, work to include furnishing and laying 9,048 ft. of 4, 6 and 8-in. cast iron pipe, including 11 double nozzle fire hydrants, special castings and gate valves, and grading of standpipe lot; for furnishing and erecting a standpipe 12x100 ft., brick pump house and standpipe foundations, 8-in. driven well to depth about 850 ft., including 6-in. strainer and all other needed material and labor; for 1 gasoline engine and triplex pump, erected and including all requisite pipe connections, etc.

Fargo, N. Dak.—The City Council has under consideration the question of installing meters and a filtration plant.

Lynchburg, Va.—The Council Com. on Water has authorized the City Engr. to make a complete survey of a route for a pipe line from here to Piney River, in Amherst Co., a distance of 25 miles.

Shenandoah, Pa.—D. G. Adelsberger, of Baltimore, has prepared plans for a system of water works, the supply to be brought from the hills 4½ miles distant.

Sterling, Colo.—Government surveyors are said to be making a preliminary survey for a ditch to carry water from Platte River to the Great Pawnee reservoir, which it is believed the government will build. Estimated cost of ditch, $1,000,000.

Aiken, S. C.—Bids are wanted Sept. 10 for constructing and drilling an artesian well. Bids to be on an 8, 10 and 12-in. well. F. W. Wessels, Chmn. Water Wks. & Street Com.

Honesdale, Pa.—An ordinance has been passed by the Town Council granting permission to the Consumers' Water Co. to construct and maintain a system of water works.

Chardon, O.—Press reports state that the B. & O. R. R. proposes to build a 15,000,000-gal. reservoir at this place. J. M. Graham, Ch. Engr., Baltimore, Md.

Baraboo, Wis.—City Engr. Kircheffer estimates the cost of building a municipal water works plant at about $85,000.

Toledo, O.—Local press reports state that the Bd. of Water Works Trus. have decided to engage G. H. Benzenberg, of Milwaukee, and Allen Hazen, of N. Y., to act on the engineers' commission and thoroughly investigate the various means of supplying the city with pure water.

Mineola, L. I., N. Y.—The Nassau County Bd. of Superv. has granted the application of the Nassau Water Co., of Manhattan, for a franchise to operate in the town of Oyster Bay.

Memphis, Tenn.—Local press reports state that the Artesian Water Co. has had plans prepared for the addition of $1,500,000 worth of new equipment for the local plant in event a new contract is made with the Co. by the city of Memphis. Plans include the installation of a duplicate main, the installation of an auxiliary system in South Memphis and 10 miles of new mains. T. T. Johnson, of Chicago, Ch. Engr.

Ithaca, N. Y.—City Clk. A. G. Marion writes that the contract for supplying the city with water by hydrants, for fire purposes, for a period of 10 years has been awarded to the Ithaca Water Works Co., Ithaca, N. Y., at $40 per hydrant, and a stipulation in contract that prices for private consumers shall be reduced per schedule to be prepared.

Cheyenne, Wyo.—City Clk. E. A. Abry writes that the following bids were opened Aug. 21 for constructing masonry dam on Middle Fork of Crow Creek: W. C. Bradbury & Co., Denver, Colo., $59,180; Olson & Toovey, Denver, Colo., $97,810; Lusk & Co., Lusk, Wyo., $58,535; Smith, Thorpe & Co., Denver, Colo., $62,495; McGarvey & Bradley, Cheyenne, $66,050; R. P. McDonald, Denver, Colo., $69,730; John Gaffy, Denver, Colo., $57,825 (awarded); J. M. O'Rourke & Co., Denver, Colo., 63,815.

Natick, Mass.—Contracts for changes and improvements in the present water works system have been awarded as follows: 3,000,000-gal. vertical, cross-compound pumping engine, to Barr Pumping Engine Co., for $20,000; 18-in. cast-iron pipe, to M. J. Drummond, at $29 per net ton; brick pumping station, to E. T. Wilson, Natick, for $11,958; collecting well, 30-ft. in diam. and 30-ft. deep, to McClellan & Hennessy, Grafton, Mass., for $9,500; covering 4,000,000-gal. open reservoir with concrete groined arch roof, to F. A. Snow, Brookline, Mass., $24,642; new 18-in. force main, about 14,000 ft. long, is being laid by day labor; whole amount to be expended, about $120,000. F. L. Fuller, Engr., Boston; Geo. W. Travis, Supt. of Water Works.

SEWERAGE AND SEWAGE DISPOSAL.

Glassport, Pa.—Bids will be received by the Sewer Com. until Sept. 2 for constructing a 4½-ft. 2-ring brick sewer on portions of Broadway and Vermont Ave., and a 12-in. terra cotta sewer on a portion of Vermont Ave., and a 24-in. terra cotta sewer on a portion of Broadway. P. S. McMullen, Boro. Engr., Glassport.

Two Rivers, Wis.—Bids will be received by the Bd. of Pub. Wks. until Sept. 17 for furnishing material and laying 20,985 ft. of 8 to 20-in. pipe sewers, 15 manholes, 29 manhole flush tanks, 18 manhole catch basins, 48 inlets and 2 outlets, 4 catch basins, including connections, etc. Eugene Allie, Chmn.

St. Paul, Minn.—Bids will be received by the Bd. of Pub. Wks. until Sept. 2 for constructing sewers in portions of several streets (Lexington Ave. sewer system), length 6,300 ft.; estimated cost, $12,000. Bids will also be received at the same time for constructing a sewer in a portion of Lafond St. John S. Grode, Pres.

The City Engr. has placed the estimated cost of Mendota St. sewer system at $7,200.

Grand Rapids, Mich.—Bids will be received by the Bd. of Pub. Wks. until Sept. 19 for constructing a public sewer, as advertised in The Engineering Record.

Waterbury, Conn.—Local press reports state that bids will be received by the City Engr. until Sept. 9 for constructing sewers in portions of 3 streets.

East Liverpool, O.—Bids are wanted Sept. 3 for the construction of 10-in. and a 6-in. sewer on West Market St.; also a 10-in. sewer on E. 7th St. and a 6-in. sewer on Green Lane, with necessary laterals, manholes and flush tanks. F. H. Croxall, Secy. Bd. of Sewer Comrs.

Cleveland, O.—Bids are wanted Sept. 17 for the construction of sewers in several streets. Chas. P. Salen, Dir. of Pub. Wks.

Terre Haute, Ind.—Bids are wanted Sept. 3 by the Bd. of Pub. Wks. for the proposed sewer on 8th St.

Trenton, N. J.—Bids are wanted Sept. 2 for the construction of sewer No. 199, through Clinton Ave., Olden Ave. and other streets. C. Edward Murray, City Clk.

Avon, N. J.—See "Water."

Hico, Tex.—This city is considering the installation of a sewerage system.

Norristown, Pa.—Boro. Engr. S. C. Corson writes that contracts for sanitary sewers in 6 streets, in all 6,300 ft. of 8-in. mains and 4,500 ft. of laterals, have been awarded to McCoy & Moore, of Bridgeport, Pa., at 78, 94, 79, 81, 73 and 58 cts. for mains, 44, 80, 54, 41 and 45 cts. for laterals, and $120 for flush tanks.

Yazoo City, Miss.—See "Water."

Denver, Colo.—B. M. Hughes, Jr., Secy. Bd. of Pub. Wks., writes that the contract for constructing sanitary sewers in South Side Sewer Dist. No. 3, has been awarded to J. M. O'Rourke, Denver, for $11,581. The contract calls for 13,490 ft. of 8-in. pipe, 47 manholes and 11 flush tanks.

Irvington, N. J.—Bids are wanted Sept. 16 for building a sewerage system, as advertised in The Engineering Record.

Lebanon, Pa.—An ordinance is said to be before the Council providing for the issue of $500,000 bonds for street and sewer improvements.

Ft. Worth, Tex.—City Engr. John B. Hawley writes that the work of constructing a sewerage system in the 5th, 6th, 7th and 8th Wards, at an estimated cost of $30,000, will be done under his supervision.

Shenandoah, Ia.—Sewers are projected in several streets. Arnold C. Koenig, N. Y. Life Bldg., Omaha, Neb., Engr. in Charge.

Boston, Mass.—Supt. of Streets Donovan has awarded the contract for furnishing and installing 6 boilers at the sewer division pumping station, Calf pasture, Boston harbor, to I. P. Morris Co., of Philadelphia, for $24,960. There were but two bids, the other being by the Atlantic Wks., E. Boston, $33,000.

Grand Junction, Colo.—Press reports state that the city sewerage system will be extended to the Teller Indian school; 10,000 ft. of 8-in. pipe will be required.

Boston, Mass.—Bids are wanted by the Boston Transit Comn. until Sept. 4 for constructing side walls and sewer in State St., as advertised in The Engineering Record.

Dunmore, Pa.—The following bids for sewer construction are stated to have been received recently by the City Council: Donohue & O'Boyle, $67,638; M. J. Gibbons, Scranton, $74,534.

Ft. Snelling, Minn.—The lowest bid received Aug. 20 by Col. Geo. E. Pond, Ch. Q. M., St Paul, for the construction of a sewer system at this post, is reported to have been from John Hankinson at $5,694, with $4 per cu. yd. extra for blasting.

Ardmore, Pa.—All bids submitted on Aug. 4 for constructing the proposed sewer system in Lower Merion have been rejected by the Township Comrs. Modified plans, which have been adopted, reduce the cost of the sewer system $16,000.

Newark, N. J.—The contract for constructing Section 3, First Division of the West Branch of the Joint Outlet Sewer (bids opened Aug. 7) has been awarded to Costa Construction Co., Orange, N. J., for $107,020.

Baker City, Ore.—The City Council has under consideration plans and estimates for a sewerage system.

Spokane, Wash.—City Engr. Gill has placed the estimated cost of a sewer system for the 2d Dist. of the 4th Ward at $69,435.

Bradley Beach, N. J.—The Boro. Council has instructed the Boro. Engr. to prepare plans, specifications and estimates of cost of constructing a municipal system of sewers.

San Francisco, Cal.—Local press reports state that bids will soon be wanted by the Bd. of Pub. Wks. for the reconstruction of sewers in the district bounded by 5th, 7th, Howard and Brannan Sts. Estimated cost, $50,000.

Richmond, Va.—The City Engr. is making surveys for the new outfall sewer which is to cost about $35,000.

Weehawken, N. J.—The Township Com. has directed Township Engr. Bond to prepare necessary data in relation to the proposed sewerage system for the relief of the lower section of the town.

Eaton, O.—The City Council is considering the construction of a sewerage system. A rough estimate places the cost at $45,000 per mile.

New York, N. Y.—Bids will be received by Jacob Cantor, Boro. Pres., until Sept. 9, for furnishing material and building an outlet sewer into Harlem River, between 92d and 93d Sts., with alterations and improvements to existing sewers in Ave. A, between 92d and 93d Sts. and in 92d St., between Ave. A and 2d Ave. Engr.'s estimate: 150 ft. of 4-ft. wooden barrel sewer, Class I; 5 lin. ft. of 4-ft. brick sewer, Class II; 1,050 ft. of 4-ft. brick sewer, Class III; 582 lin. ft. of 4-ft. brick sewer, Class IV; 13 lin. ft. of 3-ft. 6-in.x2 ft. 4-in. brick sewer, Class V; 200 lin. ft. of 3-ft. 6-in.x2-ft. 4-in. brick sewer, Class VI; 1,000 cu. yds. of rock to be excavated and removed, 50,000 ft. B. M. of timber and planking for bracing and sheet piling, etc. Bids will also be received at the same time for furnishing material and constructing a sewer in 184th St., between Bway. and Amsterdam Ave. Engr.'s estimate: 371 lin. ft. of 3-ft. 6-in.x 2-ft. 4-in. brick sewer, Class I; 100 lin. ft. of 3-ft. 6-in.x2-ft. 4-in. brick sewer, Class II; 692 lin. ft. of 12 and 15-in salt-glazed, vitrified stoneware pipe sewer; 2,050 cu. yds. of rock to be excavated and removed; 5,000 ft. B. M. of timber for bracing and sheet piling.

Cincinnati, O.—Bids will be received by the Bd. of Pub. Service until Sept. 3 for constructing sewers and drains in a portion of Innes Ave. Geo. F. Holmes, Clk.

McKeesport, Pa.—Bids will be received by R. A. Hitchens, City Comp., until Sept. 2 for constructing 12 and 15-in. terra cotta sewers in portions of several streets.

Youngstown, O.—Steps are about to be taken to give the residents in the northern and eastern portions of the city increased accommodation in the way of sewer connections.

Clifton Heights, Pa.—Governor Stone has granted a charter to Gideon Boericke, Robert W. Emorton and Louis L. Tafel, for a corporation to be known as the Delaware County Sewer Co., for the purpose of the construction and maintenance of sewers, culverts, etc., for surface and under-surface and sewage drainage in the Boroughs of Clifton Heights and Aldan and vicinity.

Rochester, N. Y.—Engr. Geo. W. Rafter has been asked by the mayor to prepare plans for a sewage disposal plant at the Elmwood Ave. contagion hospital.

Pasadena, Cal.—The City Engr. is said to be making surveys for the outfall sewer, which is to cost $35,000.

Middletown, Pa.—See "Railroads."

New Orleans, La.—Geo. G. Earl, Supt. of the Sewerage & Water Bd., has recommended that the bid of John Dowdle at $349,932 be accepted for Contract B, main sewer work, provided that he will agree to permit such pipe sewer work as the Bd. may determine, to be done under his contract as extra work under the terms of the contract and the direction of the engineer. Most of the other sewerage contracts for which bids were opened Aug. 12 have been recommended for rejection as too high; new bids recommended to be asked.

New Britain, Conn.—Engr. Wm. H. Cadwell writes that the following bids were opened Aug. 18 for constructing Section 1 of the New Britain proposed disposal system, which includes building 31 filter beds complete, requiring the removal or handling of approximately 130,000 cu. yds. of materials, the laying of about 7 miles of underdrains, one mile of 24-in. main trunk feed sewer, 95 cu. yds. of rubble mason work, 2 screen chambers complete, ½ mile of effluent ditches, 1,000 cu. yds. of screened gravel for driveways, 4,500 sq. yds. of turfing, 19 manholes, etc.: Jas. F. Gaffney, Waterbury, Ct., $31,250; Edward Balf Co., Hartford, Ct., $42,952; Robt. D. Maynard, Springfield, Mass., $41,437; Long & Little, Leominster, Mass., $36,012; Bruno, Solomone & Petits, East Boston, $54,752; C. B. & F. A. Cadwell, New Britain, $42,686; Seymour & Newell, Springfield, Mass., $40,909. Contract awarded to Jas. F. Gaffney.

Hartford, Conn.—The following bids were opened Aug. 13 for sewer construction, the work to include 12,000 ft. of 10 to 24-in. pipe sewer and 40 manholes; the trench to average 12 ft. in depth and be excavated in gravel and clay: A, Seymour & Newell, Springfield, Mass., $31,582; B, Michael O'Neil, Hartford, $31,366; C, Chas. H. Slocomb, Hartford, $34,081; D, Smith & Price, Hartford, $35,801; E, Hartford Paving & Const. Co., Hartford, $29,546 (awarded). For detail bids see accompanying table:

Bidders.	24-in. tile.	20-in. tile.	18-in. tile.	15-in. tile.	12-in. tile.	10-in. tile.	Manholes.
A....	$3.45	$2.25	$1.60	$1.50	$1.50	$1.00	$42
B....	3.11	2.47	1.59	1.36	1.64	.74	45

BRIDGES.

Salem, Mass.—The Co. Comrs. have been petitioned to widen and improve the bridge across Crane River.

Chisholm, Minn.—Jacob Zimmerman, of Duluth, is reported to have secured the contract to construct a bridge across Lonyear Lake in this city, for $9,849.

St. Paul, Minn.—The Bd. of Aldermen has been petitioned to have the engineering department prepare plans and specifications for extending 3d St. bridge to Maria Ave. There is $65,000 available for this work, and it is stated that the total cost will be about $125,000.

Pasadena, Cal.—City Engr. Allin estimates the cost of constructing the proposed boulevard bridge across Arroyo Seco, about 800 ft. south of Madeline driveway, as follows: For a 210-ft. steel highway bridge, with 6-ft. sidewalks and 20-ft. roadway, $10,000; with a 30-ft. roadway, $16,000, and with a 40-ft. roadway, $25,000.

Mifflinville, Pa.—The King Bridge Co. is reported to have secured from C. H. Reimard, of Bloomsburg, the sub-contract for the superstructure of the Mifflinville bridge for $56,660.

Renfrew, Ont.—Thos. McLachlin is reported to have secured the contract to construct a bridge across Bonnechere River, Renfrew Co., for $16,500.

Pittsburg, Pa.—Frank H. Schwartz, Supt. of the Bureau of Construction, reports that the Point Bridge across Monongahela River is in an unsafe condition and that it will require $150,000 to repair it.

New Britain, Conn.—The construction of 2 concrete bridges, 1 at Chapman St. and the other at Plainville road, is contemplated.

Milwaukee, Wis.—Plans are being prepared for a bascule bridge to be built at W. Water St.

Bridgeton, N. J.—The Bd. of Freeholders is considering replacing the West Creek bridge with a stationary or draw bridge.

Buffalo, N. Y.—Bids are wanted Sept. 4 for constructing abutments and wing walls for Sprenger Ave. bridge. Francis G. Ward, Comr. of Pub. Wks.

Knoxville, Tenn.—J. C. Monday & Co., of Knoxville, are reported to have received the contract to construct the stone work on the Clinch River bridge, on the Knoxville, LaFollette & Jellico R. R., for about $60,000.

Allegheny, Pa.—Bids are wanted Sept. 9 for the construction and erection of the superstructure of a bridge on Shady Ave. over Woods Run Valley; also for the construction of piers and abutments for same bridge; also for paving the roadway and sidewalks of said bridge. John R. Murphy, City Recorder.

Downieville, Cal.—Bids are wanted Sept. 15 by Henry E. Quigley, Clk. Bd. of Superv., for a combination bridge with 8 piers.

Washington, Ind.—Thos. Harris, Clk. Daviess Co. Court, writes that at the election held Aug. 19 it was voted to construct a bridge over White River between Knox and Daviess Counties.

Anadarko, Okla. Ter.—Co. Surveyor Chas. H. Jones writes that the contract for constructing 5 steel bridges (bids opened Aug. 18) has been awarded to the Wichita Bridge & Iron Co., Wichita, Kan., for $13,621.

Harrisburg, Pa.—Local press reports state that the State Bd. of Property has decided to ask for bids for constructing 21 county bridges, which will replace structures swept away by the floods of last winter. It is stated that the cost of the bridges will range from $5,000 to $15,000 each. The following are reported to have been appointed as engineers in charge of construction: Emil Swenson, of Pittsburg, 1 bridge in Juniata Co. and 2 bridges in Lycoming Co.; H. Laub, of Pittsburg, bridges in Forest, Clearfield and Jefferson Counties; R. Bowman, of Mahanoy City, 1 Berks Co. bridge; A. J. Whitney, of Rome, a bridge in Bradford Co.; Oscar E. Thompson, of Phoenixville, on the following bridges: 2 in Bradford Co., 2 in Wyoming Co., 5 in Wayne Co., 1 each in Carbon, Luzerne, Sullivan and Lackawanna Counties.

Philadelphia, Pa.—The City Bureau of Surveys is reported to be contemplating the construction of an approach from the highlands east of Ridge Ave. to connect the proposed upper deck of the Falls bridge and also an approach to connect the upper deck with the River Drive.

Doylestown, Pa.—Ch. Webster, of the Bureau of Surveys, and the Co. Comrs. are considering replacing present stone structure at Frankford Ave. with a steel bridge with stone piers and approaches, at a cost of about $20,000.

Boston, Mass.—City Engr. Jackson has awarded the contract for building the three remaining masonry and concrete piers for Broadway bridge (bids received Aug. 27) to Holbrook, Cabot & Rollins, of Boston, at $35,969. There were five other bidders: Lawler Bros., $36,465; Jones & Meehan, $39,197; W. L. Miller, $38,643; Wm. H. Ellis, $44,556; John T. Cavanagh, $45,000.

Wilmington, Del.—Bids will be received by John G. Armstrong, Co. Comr., until Sept. 2 for constructing the superstructure of a steel highway bridge to consist of 1 span 54 ft. long, across Christiana River, 1 mile from Newark station.

Hackettstown, N. J.—The Co. Bd. of Freeholders has decided to replace the line bridge between Warren and Morris Counties with an iron bridge, to have an 80-ft. span and 20-ft. roadway.

Cleveland, Ill.—The building of a wagon bridge across Rock River at Cleveland, connecting Henry and Rock Island Counties, is being considered.

Dyersville, Ia.—The Clinton Iron & Bridge Co., of Clinton, Ia., is reported to have secured the contract to construct a bridge at Dyersville for $5,090.

Connellsville, Pa.—The Glenwood Bridge Co. has applied to the Baltimore & Ohio R. R. Co. for permission to construct a bridge, 1 mile long, across the Co.'s yard at Connellsville.

Brenham, Tex.—Press reports state that a $3,000 iron bridge across New Year's Creek has been washed away by the freshets.

Williamsport, Md.—The citizens of Williamsport have petitioned the Co. Comrs. to construct a bridge across Potomac River, connecting Williamsport with Berkeley Co., W. Va. It is stated that if the Co. Comrs. do not make an appropriation for the construction of said bridge, the citizens will endeavor to form a stock company and build a bridge at a cost of about $30,000.

Oklahoma City, Okla. Ter.—It is stated that the Choctaw Northern R. R. Co. has decided to build this fall a $20,000 viaduct across its tracks at Walnut St. F. A. Molitor, Ch. Engr., North Little Rock, Ark.

Syracuse, N. Y.—An agreement has been reached between the city and the officials of the D., L. & W. R. R., whereby the company is to move a portion of its coal sheds at the foot of Butternut St. to permit the city to extend the street across the canal. The wooden structure now there will be replaced with a steel trestle with supports, and the city has agreed to pay $5,000 toward the cost of removing sheds and constructing trestle.

Oakland, Cal.—Cotton Bros. & Co., of Oakland, are reported to have received the contract to replace Bay Farm Island bridge, at $19,000.

Luray, Va.—Bids will be received by the Town Council until Sept. 15 for stone and concrete masonry for bridge over Hawksbill Creek; 1 span, 105 c. to c., end pins, 18-ft. roadway. T. R. Campbell, Mayor.

Culpeper, Va.—Bids will be received by the Co. Bd. of Superv. until Sept. 3 for erecting 2 iron bridges. Address W. E. Coons, Clk.

Terre Haute, Ind.—Bids will be received by the Co. Comrs. until Sept. 20 for constructing a 70-ft. span bridge at 7th St., Harrison Township; a 30-ft. span bridge and a masonry bridge, both in Linton Township; and a 60-ft. span bridge in Pierson Township. Jas. Soules, Co. Aud.

PAVING AND ROADMAKING.

Mt. Clemens, Mich.—Local press reports state that the Council has asked for bids for repaving Cass Ave., Walnut St. and several other streets.

Dallas, Tex.—Local press reports state that bids have been asked for paving with asphalt on Commerce St.

St. Joseph, Mo.—Two new paved thoroughfares in the resident district are among the important contracts which, it is stated, are to be let in the near future by City Engr. Floyd, in compliance with ordinances passed and signed.

Glassport, Pa.—Bids will be received by the Boro. Street Com. until Sept. 2 for paving, grading and curbing Broadway. W. F. Sparks, Chmn.; P. S. McMullen, Boro. Engr., Glassport.

New York, N. Y.—Bids are wanted Sept. 9 for repairing and maintaining asphalt pavements, on numerous streets on which the original maintenance guarantee has expired. Engr.'s estimate, 15,000 sq. yds. of asphalt block pavement and 5,000 cu. yds. of concrete, including mortar bed. Bids will also be received at the same time for regulating and repaving portions of numerous streets. Engr.'s estimate, 74,790 sq. yds. of asphalt pavement, including binder course, 73,770 sq. yds. of stone pavement, to be relaid as foundation, or in approaches, etc., 37,041 lin. ft. of new curbstone, etc. Jacob A. Cantor, Boro. Pres.

Camden, N. J.—Bids will be received by Chas. H. Ellis, Jr., Chmn. Com. on Streets & Highways, until Sept. 2 for paving with vitrified brick on a concrete foundation portions of several streets.

Terre Haute, Ind.—Robt. H. Sparks, City Engr., writes that bids will be received until Sept. 5 for repairing the asphalt pavement on 5th and 7th Sts.

Grossepointe, Mich.—Bids will be received until Sept. 6 by the Township Bd. and Highway Comr. for paving with macadam on a portion of Jefferson Ave. Chas. Poupard, Highway Comr.; Thos. Campau & Son, Engrs., Rm. 3, Campau Bldg., Detroit.

Lawrence, Kan.—Sam P. Moore, City Clk., writes that bids will be received until Sept. 2 for paving with macadam, 8-in. thick, approximately 10,000 sq. yds. on Ohio St.; 5-ton roller. Holland Wheeler, City Engr.

Toledo, O.—Bids are wanted Sept. 8 for block paving in Crane Lane. Chas. H. Nauts, City Clk.

Connersville, Ind.—City Engr. Karl L. Hanson writes that the contract for 65,000 sq. ft. of cement sidewalk has been awarded to Chas., Jr., and Roy Williams, of Connersville, at 9½ cts. per sq. yd.

Alton, Ill.—Petitions are being circulated for the paving of Liberty, Grove and Common Sts. with brick, in all about 1 mile long. Property owners in Bloomfield St. have petitioned for brick sidewalks about 1½ miles in length.

Lebanon, Pa.—See "Sewerage and Sewage Disposal."

Kenosha, Wis.—A movement is said to have been started for the construction of a boulevard paved with macadam or asphalt between Kenosha and Racine. Total length, 8 miles.

New York, N. Y.—Bids are wanted Sept. 4 for the completion of the construction of Riverside Park and Drive, between 95th and 99th Sts., in connection with the 96th St. viaduct. Wm. R. Willcox, Comr. of Parks.

Cincinnati, O.—Bids are wanted Sept. 18 for repairing a portion of Race St. with asphalt; also for improving Huron St. by paving with brick. Geo. F. Holmes, Clk. Bd. of Pub. Service.

Baltimore, Md.—Bids are wanted by the Bd. of Awards Sept. 3 for grading, paving with Belgian block and curbing Henry St. B. T. Fendall, City Engr.

Bradford, Pa.—City Clk. E. C. Charlton writes that the contract for paving Sanford, Petrolia and Pearl Sts. with brick, has been awarded to Sheehan & McGhaw, for $20,000.

South Bend, Ind.—City Engr. A. J. Hammond has been directed by the Bd. of Pub. Wks. to prepare plans for paving the alley along the new city hall with sheet asphalt, bituminous macadam or rock asphalt.

Cedar Rapids, Ia.—Bids are wanted Sept. 5 for paving with macadam on a portion of 16th Ave. West. W. L. Cherry, Chmn. Pub. Improv. Com.

Leavenworth, Kan.—Bids are wanted Sept. 3 for 8,650 lin. ft. of artificial stone curbing, cost not to exceed 52 cts. per lin. ft. Bids will also be received at the same time for regrading and paving 4th St., requiring 19,063 sq. yds. of paving and 6,615 cu. yds. of regrading, cost not to exceed $1.47 per sq. yd. and 30 cts. per cu. yd. respectively. M. A. Przybylowicz, City Clk.

New Haven, Conn.—City Engr. Kelly estimates the cost of repairing East Chapel St. pavement at $10,500.

Peru, Ind.—The City Council has ordered paved with brick the alleys one square east and west of Broadway. Estimated cost, $20,000.

Utica, N. Y.—The contract for paving the eastern end of Broad St. has been awarded to the Barber Asphalt Paving Co. for about $11,500.

Linden, Tex.—The Commissioners Court has authorized the issue of $10,000 bonds for the improvement of roads and bridges in Cass Co.

Fritchey, of Lancaster, Pa., at his bid of $1.97 per sq. yd. for Mack block, $1.12 per ft. for dressed granite curbing, 20 cts. per ft. for old granite curbing and 10 cts. per sq. yd. for repairing with old rubble stone; total, about $20,000.

Grossepointe, Mich.—The Township Bd. has awarded the contract for macadamizing Mack Ave. to Gilbert Moran & Co. for about $34,000.

Lincoln, Neb.—The Council has awarded the contract for asphalt surfacing in repaving Districts Nos. 14, 18, 19, 20 and 24, to the Green River Rock Asphalt Co. at $1.51 per sq. yd., with 10-year guarantee.

Peoria, Ill.—The contract for paving S. Adams St., nearly one mile in length, has been awarded to Thompson & Case for $38,388.

St. Mary's, O.—Thos. McKinney & Son, of Toledo, are reported to have received the contract for paving Wayne St., nearly a mile long, at their bid, which amounted to about $43,000. Logan brick to be used.

Monmouth, Ill.—The Council has passed an ordinance for constructing 13 blocks of brick and cement sidewalks.

Athens, Tex.—Representatives of the people of several counties interested, at a meeting held recently in Athens, pledged $500,000 with which to build a road from Palestine to Greenville.

Mexico, Mo.—The Council is said to be taking steps to pave certain streets with brick.

Menominee, Mich.—According to press reports the citizens have decided to pave several streets with brick.

Erie, Pa.—The contract for paving a portion of 21st St. has been awarded to Mayer Bros. at $1.97 per sq. yd. for sheet asphalt; maintenance, $12.50 per 1,000 yds. for 10 years; landmarks, etc., $5; 6-in. pipe at 45 cts.

Washington, D. C.—The Dist. Comrs. have determined to resurface East Capitol St. and other public thoroughfares.

Indianapolis, Ind.—The Western Construction Co. has been awarded the contract for a flint rock macadam roadway and curb in Shelby St. at $3.28 per lin. ft.

Nashville, Tenn.—A bill before the Bd. of Pub. Wks. provides for the appropriation of $39,400 to pave with bituminous macadam Summer, Carroll, Mulberry, Center, College and Market Sts., as recommended by Mayor Head.

Appleton, Wis.—A plan is on foot to macadamize the thoroughfare between this city and Menasha.

Buffalo, N. Y.—See "Electric Railways."

Cincinnati, O.—The City Engr. has been directed to prepare specifications for the resurfacing of a portion of 4th St. with sheet asphalt.

Hendersonville, N. C.—Bids will be received at the office of the Mayor until Sept. 12 for grading, curbing and paving, as advertised in The Engineering Record.

Bedford, Ind.—At the special election held in this township Aug. 16 it was voted to construct at once 36 gravel roads.

Atchison, Kan.—The Council has passed a resolution to grade, curb and pave with brick a portion of Santa Fe St.; 2,533 sq. yds. paving and 1,360 lin. ft. cement curbing.

Bids are wanted Sept. 2 for grading, curbing and paving a portion of 10th St.; 3,900 sq. yds. brick paving and 2,460 lin. ft. cement curb 5½x20 in. Fred Giddings, City Engr.

The City Engr. has been instructed to prepare plans for repaving Commercial St. with vitrified brick on concrete foundation. There will be required 18,700 sq. yds. of paving and a large amount of new curb.

Covington, Ky.—The Council has passed an ordinance providing for the paving of a portion of Pike St. with brick.

Muskegon, Mich.—City Engr. C. S. Gamble writes that the contract for paving Muskegon Ave., length 3,925 ft., has been awarded to the Barber Asphalt Paving Co. at $1.49 per yd. for Trinidad pitch lake asphalt and macadam 8 in. thick; 46 cts. per ft. for 7,231 ft. of cement curb and gutter. Total, $19,200.

Oskaloosa, Ia.—It is stated that bids are wanted Sept. 3 for 21,000 sq. yds. of brick paving, 10,000 ft. of curbing, grading, etc. C. Leighton, City Clk.

Spokane, Wash.—It is stated that bids are wanted Sept. 8 for paving, curbing and guttering of Main St. R. E. Clark, Secy. Bd. Pub. Wks.

Eureka, Cal.—It is stated that bids will be received by the Bd. of Superv. until Sept. 8 for constructing the Auger Road.

Niles, O.—It is stated that bids are wanted Sept. 18 for 3,200 lin. ft. of sandstone curbing and 7,000 sq. yds. of asphalt block pavement. Wm. Wilson, City Engr.

North Bend, O.—It is stated that bids are wanted Sept. 15 for $10,000 street improvement bonds and $10,000 sidewalk bonds. W. D. McClurkin, Hamlet Clk.

Janesville, Wis.—Bids will be received by the Street Assessment Com. until Sept. 20 for grading to a subgrade and surfacing with macadam on portions of several streets. Victor P. Richardson, Chmn.

Decatur, Ind.—It is stated that bids are wanted Sept. 4 for constructing Brushwood macadam road. Estimated cost, $5,600. Abe Boch, Co. Aud.

Green Bay, Mich.—It is stated that bids are wanted by the Com. on Streets until Sept. 16 for grading, curbing and paving with asphalt on Cherry St., requiring about 3,182 sq. yds. of asphalt pavement and 1,380 lin. ft. of curb and gutter.

Schenectady, N. Y.—Local press reports state that bids will be received by the City Council until Sept. 9 for paving a portion of College St.

Newton, N. J.—The Bd. of Chosen Freeholders has appropriated $20,000 for building macadam roads with State aid.

St. Louis, Mo.—Pres. Phillips, of the Bd. of Pub. Improv., estimates that not less than 125 miles of streets will be reconstructed or newly paved during 1903.

Boston, Mass.—City Engr. Jackson will open bids on Sept. 10 for building a telford macadam roadway in Oakland St. in the Mattapan Dist.

St. Paul, Minn.—Bids will be received by the Bd. of Pub. Wks. until Sept. 2 for paving with brick on a portion of Robert St. Estimated cost, $22,790. Bids are also wanted Sept. 2 for paving Ramsey St. with asphalt. R. L. Gorman, Clk.

Local press reports state that the following bids were opened Aug. 20 for paving W. 7th St. from Ramsey St. to Tuscarora Ave., 39,258 sq. yds., with sandstone. The first amount in each bid is the city's portion, the second amount the street railway's portion: P. M. Hennessy, $96,875, $11,900; L. G. Washington, $98,875, $11,465; James Forrestal & Co., $97,360, $11,670; Fielding & Shepley (awarded), $92,600, $10,600.

Paris, Ill.—City Engr. W. C. Lemen writes that the following bids were opened Aug. 14 for 15,200 sq. yds. of brick paving on concrete foundation, 2,000 lin. ft. of stone curbing, 6,100 ft. of combined curb and gutter, for Wood St.: A, D. W. Norton, $26,750; B, Troy Porter, $28,054; C, Morrisey & Lynch, $25,778; D, Wolf, Maupin & Curdie, $25,493; E, Thompson & Case, $25,320; F, Capitol Paving & Const. Co., $26,125; G, Geo. R. Grimes, $27,497; Engineer's estimate, $29,172. For detail bids see accompanying table:

Boston, Mass.—Supt. of Streets Donovan has received the following bids for paving Merrimac St., between Haymarket square and Causeway St., with granite blocks, pitch joints, and concrete base: Wm. J. Barry, $11,042; Wm. J. Rafferty, $9,397; Edw. J. Hayden, $13,076; Dan. E. Lynch, $13,279; Dan. J. Kiley, $11,731; P. McGovern, $13,490; J. J. Sullivan, $10,308; W. H. Ellis, $11,253; P. H. Bradley, $9,451; J. B. O'Rourke, $11,864; Benj. M. Cram, $12,079. Barnes-Ruflin Co., $10,033. Contract awarded to Wm. J. Rafferty.

Chanute, Kan.—City Engr. of Coffeyville, Kan., E. H. Ricksecker writes that the contract for paving Main St. with brick (bids opened Aug. 18) has been awarded to Stevens, Shulty & Co., Ft. Madison, Ia., as follows: Excavating, at 25 cts. per cu. yd.; crushed stone, $1.50 per cu. yd.; 5-in. curbstone, at 68 cts. per lin. ft.; paving complete, at $1.57 per sq. yd.; sewer pipe laid, 24-in. at $1.40, 18-in. at 75 cts., and 12-in. at 43 cts.; total, $22,181. Other bids received were as follows, prices given being per sq. yd. for paving, and total, respectively: R. S. Gilfellen, Ft. Scott, Kan., $1.85, $26,136; John Ritche, Topeka, Kan., $1.88, $26,560; W. A. Stuckey, Guthrie, Okla. Ter., $1.62½, $22,958; Ramsey & Ramsey, Topeka, Kan., $1.80, $25,430; W. M. Edwards, Kansas City, Mo., $1.87, $26,419; Hanly & McGuire, Leavenworth, Kan., $1.90, $26,843; O. C. Chapin, Leavenworth, Kan., $2, $28,250.

POWER PLANTS, GAS AND ELECTRICITY.

National Home, Wis.—Bids are wanted Sept. 22 for furnishing material and labor necessary for the extension of the electric light plant at this home. Cornelius Wheeler, Governor.

Somerset, Ky.—Mayor F. S. Griffin writes that this city will erect an electric light plant, or sell a franchise and buy light, the latter plan being preferred. It is desired to include franchise for the construction of cold storage plant and electric railway.

Colby, Wis.—See "Water."

Smyrna, Del.—Consulting Engr. T. Chalkley Hatton, of Wilmington, Del., writes that it is proposed to improve the electric light plant at a cost of $5,000. S. A. Anthony, Chmn. of Com.

Eureka, Kan.—The Council is stated to have granted the Eureka Gas & Mineral Co. a franchise for a term of 20 years. It is stated that probably 4 wells will be sunk this summer and gas will be piped to the town before winter.

Cape May, N. J.—The Cape May Light & Power Co. has been incorporated, with a capital of $150,000, by Edw. C. Brainard, Chicago; Edw. F. Mandeville, Camden, and Jas. M. E. Hildreth, Cape May, to operate an electric plant at Cape May.

Ephrata, Pa.—The citizens are stated to have voted Aug. 19 to issue $15,000 bonds for an electric light plant.

Jamestown, N. Y.—The Jamestown Lighting & Power Co. has been incorporated, with a capital of $100,000. Directors: Ernest L. Carr, Melrose, Mass.; Walter E. Griggs, Jamestown, and others.

Asti, Cal.—The Cloverdale Light & Power Co. is reported incorporated, with a capital of $100,000, to supply electric light and power in Cloverdale, Asti, Geyserville and other places. Principal office to be at Asti. Incorporators: A. Sbarboro and F. C. Rossi.

Laramie, Wyo.—The Council has granted Jay Burns, of Omaha, Neb., a franchise for a gas plant.

Chicago, Ill.—By the merging of the Northwestern and Cicero gas companies all the gas plants in Cook County outside of Chicago were brought under one ownership Aug. 20. The name of the new organization is the Northwestern Gaslight & Coke Co., and its capital is $10,000,000. The plans of the new company are to at once build a large central plant in Cicero, and for this purpose an issue of bonds has been authorized by the directors. Nelson A. McCleary, Pres., Chicago.

Williamsville, N. Y.—The Council is stated to have granted Lafferty & O'Donnell, of Bradford, Pa., a franchise to lay pipes and supply the town with natural gas for lighting and heating purposes.

St. Boniface, Man.—See "Water."

Dryden, N. Y.—The Village Trus. are stated to have selected an engineer to investigate the conditions here and make an estimate on the cost of establishing an electric light system.

Superior, Wis.—The Highland Canal & Power Co. is stated to have petitioned the Council for a franchise to set up its line and operate in this city.

Wheaton, Minn.—The Wheaton Electric Light Co., of Wheaton, has been incorporated, with a capital of $25,000. Incorporators: W. I. Gray, Minneapolis; F. W. Murphy and M. J. Jacobson, of Wheaton.

Cordelia, Cal.—The Bay Counties Power Co. is reported to be surveying a route from this point to Napa Junction, where the company will build a line to transmit electricity to operate the machinery in the cement works.

Baldwinsville, N. Y.—The Baldwinsville Light & Heat Co. has been incorporated, with a capital of $100,000, to manufacture and supply gas, natural and artificial, and to manufacture and supply electricity in Baldwinsville, Lysander and Van Buren. Directors: W. F. Morris, Jacob Amos, and others, all of Baldwinsville.

Ulen, Minn.—Village Recorder C. Paulson writes that at the election held Aug. 20 it was voted to construct an electric light plant.

Tucumcari, N. Mex.—Theo. W. Heman, Secy., writes that the Tucumcari Electric Light & Water Co. is now developing the water power and later will install an electric light plant. C. H. Rankin, Pres.

Barberton, O.—T. W. Shelton, of Akron, Supt. St. Dept. of Northern Ohio Traction Co., writes that said company proposes to construct a power and light plant in Barberton, at a cost of $15,000. There will be required 100 fuse boxes, 50 series a. c. arc lamps, 60 cycle on a 4,000 volt circuit, 16 miles 0 wire, 1,000 glass insulators, 200 meters, 100 transformers, etc. There will be no buildings, as the current will be furnished from the Akron power house.

Chicago, Ill.—Bids are wanted Sept. 3 for furnishing material and constructing a conduit on Halstead St. Edw. B. Ellicott, City Electrician.

Belleville, Ill.—The plant of the Belleville Gas Light & Coke Co. is stated to have been purchased by M. M. Stevens, L. D. Turner, Jr., and others, of East St. Louis, Ill. They propose making improvements and extending the gas mains and electric wires.

Big Stone Gap, Va.—It is stated that bids will be received about Sept. 12 for constructing an electric light plant, to cost $12,000. The plant is to have a capacity of about 50 arc and 750 incandescent lights. C. L. Hamblen, Mayor.

Washington, D. C.—Bids will be received by the Comrs. D. C. until Sept. 6 for lighting the public streets, alleys, avenues and roads in the Dist. of Columbia during the year ending June 30, 1903, with naphtha lamps. Wm. Tindall, Secy.

Castile, N. Y.—The citizens are stated to have voted Aug. 26 to install an electric light plant, at a cost of $10,500.

Niagara Falls, Ont.—A press report states that the Ontario Power Co. will proceed at once to construct a temporary cofferdam at Dufferin Island on the Niagara River. A permanent structure will be placed inside the temporary dam, and the latter must be removed not later than June 1, 1903.

Yazoo City, Miss.—See "Water."

Indianapolis, Ind.—John W. and Edw. Schmidt, Proprietors of the Century Bldg., are about to make application to the Bd. of Pub. Wks. for a franchise to furnish electricity for light and power, steam and hot water for heating purposes and cold water in the district bounded by North, South, East and West Sts.

San Francisco, Cal.—The Tonopah Light & Power Co. has been incorporated, with a capital of $50,000. Directors: W. C. Watson, W. C. Waller, and others.

Flint, Mich.—Mayor Alvord is stated to have signed the ordinance granting the Pearce Construction Co., of Chicago, Ill., a franchise to construct and operate a light and heating plant.

Macon, Ga.—Local press reports state that bids will be received by the City Council until Nov. 1 for lighting the city with electric lights for a term of 5 years.

Honeoye Falls, N. Y.—The Ontario Gas Co. has been incorporated, with a capital of $50,000, to bore, drill and operate for petroleum and gas and also to lay and maintain pipe lines and supply gas for light, heat and power in the towns of East and West Bloomfield, Mendon and Lima and in the villages in these towns. Directors: A. Miner Wellman and H. A. Corbin, of Friendship, N. Y.; E. M. Lockwood, of Kansas City, Mo., and others.

ELECTRIC RAILWAYS.

Seekonk, Mass.—The Selectmen are stated to have granted a franchise to the Bristol County Ry. Co. D. A. Brooks, Mgr., 53 State St., Boston.

Salamanca, N. Y.—The Village Trus. are stated to have granted a franchise to the Salamanca & Little Valley Traction Co.

West Superior, Wis.—The Duluth-Superior Traction Co. is stated to have decided to extend its line from the steel plant in Superior to Billings Park, a distance of about a mile; also to erect an addition to its car barns in Duluth, to cost $15,000, and to erect a new car barn in Superior, to cost $30,000. It is reported also that numerous extensive improvements will be made at Duluth. C. G. Goodrich, Pres., Minneapolis, Minn.

Greenville, Pa.—The East End St. Ry. Co., of Sharon, is stated to have secured a franchise in Greenville.

Salt Lake City, Utah.—The Co. Comrs. are stated to have granted the Salt Lake & Utah Valley Ry. Co. a franchise to construct a street railroad from the city limits on the south at highway No. 17, along the Redwood road to Bingham Junction.

Nashville, Tenn.—The Nashville Ry. Co. is considering the extension of the Jefferson St. line 2 miles to connect with the W. Nashville line. N. P. Yeatman, Secy., Nashville.

Hamilton, O.—The Mill Creek Valley St. Ry. Co. is reported to have decided to extend its line from Hamilton to Middletown. W. G. Wagenhals, Mgr., Cincinnati.

Danville, Ill.—The Danville, Urbana & Champaign Ry. Co. has been incorporated, with a capital of $250,000, to construct an electric railway from Danville through Vermilion, Champaign, Piatt, Macon and Sangamon Counties to Springfield. Incorporators: Roy Wright, Urbana; Thos. G. Wood, Champaign, and others.

Pennington, N. J.—Wilbur F. Sadler, of Trenton, is reported interested in the construction of an electric railway between Pennington and Trenton.

Muncie, Ind.—The Muncie & Portland Interurban Ry. Co. (G. O. Driscoll, Pres., Muncie) is about to begin the survey and location of its road.

Somerset, Ky.—See "Power Plants, Gas and Electricity."

Saratoga, N. Y.—J. S. Mott & Son are making a survey for a trolley road from Saratoga to Schuylerville, a distance of 12 miles.

Bristol, Conn.—Boro. Clk. D. J. Heffernan writes that on Aug. 21 the Boro. Bd. voted to grant a permit to the Bristol-Plainville Tramway Co. to construct the Terryville extension.

St. Marys, O.—The Western Ohio Ry. Co. is stated to have decided to extend its line from St. Mary's west through Rockford and Ohio City, Ind., to Decatur and Ft. Wayne. F. D. Carpenter, Gen. Mgr., Lima, O.

Paris, Ky.—The Bourbon Co. Comrs. are stated to have granted the Bluegrass Traction Co. a franchise for an electric railway between Lexington and Paris.

Cazenovia, N. Y.—Jas. R. Barrett, of Cazenovia, is stated to have petitioned the Village Trus. for a franchise.

Charlestown, W. Va.—A charter is stated to have been granted to the Charlestown, Berryville & Winchester St. Ry. Co. to construct an electric railway to connect the places mentioned; capital, $500,000. Incorporators: Geo. E. Yester, Hagerstown, Md.; R. P. Chew, Charlestown, and others.

Andover, O.—The City Council is stated to have granted a franchise to the Conneaut Southern Electric Ry. Co.

New Castle, Pa.—It is stated that the New Castle Traction Co. will extend its Pittsburg line a mile toward the city limits.

San Bernardino, Cal.—The San Bernardino Power Co. is reported incorporated, with a capital of $300,000, to construct and operate an electric railway north on E St. from 3d and then to Highland. Directors: W. E. Harris, S. F. Kelley, and others.

Riverside, Cal.—H. A. Duryee, representing the San Bernardino Traction Co., is stated to have secured a franchise for an electric railway.

Buffalo, N. Y.—The Crosstown St. Ry. Co. is stated to have secured from State Engineer Bond a permit for the construction of a double track in the Hamburg road, from the crossing of the Buffalo, Rochester & Pittsburg tracks to Limestone Hill. The company is to macadamize the road 12 ft. on each side of its rails. Benj. Franklin, Pres., Buffalo.

Hoosick, N. Y.—The Highway Comrs. are stated to have granted the Bennington & Hoosac Valley Ry. Co. permission to extend its line through the town of Hoosick, a distance of about 12 miles. E. H. Libby, Supt., Hoosick Falls.

Trenton, N. J.—The Camden & Trenton Traction Co. is stated to have petitioned the City Council for permission to extend its line into the center of this city. M. B. Perkins, Mgr., Beverly.

Sharon, Pa.—The Sharon & West Middlesex St. Ry. Co. has been incorporated, with a capital of $50,000, to construct a line 4 miles in length. R. Montgomery, Pres., Youngstown, O.

Cressey, 800 Broad St., to prepare plans for a 14-room addition to Bergen St. school, to cost $35,000; Hooper & Co., 238 Washington St., for a 4-room addition to the Roseville school, to cost $10,000; and Gustav Staehlin, 238 Washington St., for an addition to the 13th Ave. school, to cost $22,500. A $32,000 school will also be erected in a locality which will afford relief to the Summer Ave. and the Elliott St. schools.

Springboro, O.—Bids are wanted Sept. 20 for erecting a school. Chas. Banta, Clk.

Hartford, Conn.—Bids are wanted Sept. 2 for the construction, and separate bids for the plumbing and heating of the proposed addition to the Wilson St. school. Hermann Lilienthal, Clk. of Com.

STREET CLEANING AND GARBAGE DISPOSAL.

Adams, Mass.—Bids will be received by the Bd. of Health until about Sept. 20 for the collection and disposal of garbage. Dr. A. Desrochers, Secy.

Oakland, Cal.—It is stated that if the Council will grant an exclusive franchise, local capitalists will form a company and build a garbage crematory having a capacity of 40 tons per day.

Racine, Wis.—Local press reports state that the following bids were opened recently for a 25-ton garbage crematory: Dixon Garbage Co., Toledo, O., 6 propositions ranging from $9,660, for wooden frame building and steel smokestack to $10,910 for brick building and chimney. Davis Garbage Furnace Co., of Lancaster, Pa., $8,600 for frame building with steel smokestack, $850 extra for brick chimney and $2,200 additional for brick building. Decarie Manufacturing Co., Minneapolis, 4 propositions ranging in price from $9,000 for frame building with brick chimney to $16,000 for all steel fire-proof plant.

Los Angeles, Cal.—The garbage contract is reported to have been awarded to Franklin & Alexander at $1,790 a month.

GOVERNMENT WORK.

New York, N. Y.—Bids are wanted Sept. 25 at the U. S. Engineer Office for dredging in Great South Bay and Patchogue River, as advertised in The Engineering Record.

Ft. Totten, N. Y.—Bids are wanted Sept. 19 for constructing addition to Guard House at this post, as advertised in The Engineering Record.

Newport, R. I.—Bids are wanted Sept. 17 at the Office of Constructing Q. M., for a frame addition to Guard House, Ft. Greble, as advertised in The Engineering Record.

Boston, Mass.—See "Water."

Washington, D. C.—Bids are wanted Sept. 4 for furnishing all material and erecting a building and elephant house and yards, etc., in the National Zoological Park. Archts., Hornblower & Marshall, 1509 H St., N. W. Richd. Rathbun, Acting Secy., Smithsonian Institute.

Washington, D. C.—Bids will be received at the U. S. Engr. Office until Sept. 26 for furnishing electrical fixtures and supplies for new building for Government Printing Office, as advertised in The Engineering Record.

Cleveland, O.—Maj. Dan C. Kingman, Corps of Engrs., U. S. A., writes that all bids opened Aug. 18, for the reconstruction and repair of parts of the east and west piers at Fairport Harbor, have been recommended for rejection, owing to high prices.

Aberdeen, S. Dak.—Bids will be received until Oct. 14 by Jas. Knox Taylor, Superv. Archt., Treas. Dept., Washington, D. C., for the construction (excepting heating apparatus, electric wiring, and conduits), of the U. S. Post Office at Aberdeen.

Brunswick, Ga.—Bids will be received until Sept. 19 by Jas. Knox Taylor, Superv. Archt., Treas. Dept., Washington, D. C., for installing a conduit and electric wiring system for the U. S. Custom House and Post Office at Brunswick.

Portland, Me.—Bids are wanted Sept. 29 for dredging in Bucksport Harbor, Camden Harbor and Georges River, Me.; also for ledge excavation at Sullivans Falls, Me., as advertised in The Engineering Record.

Newport News, Va.—Bids will be received by the Superv. Archt., Treas. Dept., Washington, D. C., until Oct. 9 for the construction (except heating apparatus, electric wiring and conduits) of the U. S. Custom House and Post Office at Newport News, as advertised in The Engineering Record.

Cleveland, O.—Bids are wanted Sept. 4 for removal of wreck of steamer "George Dunbar" in Lake Erie. Maj. Dan. C. Kingman, Corps Engrs., U. S. A.

Philadelphia, Pa.—The contract for erecting a pattern shop and storehouse addition to the steam engineering building at League Island Navy Yard has been awarded to the Penn Erecting Co., Philadelphia; it will be a 2-story steel fire-proof structure, 65x103 ft.

Philadelphia, Pa.—Bids will be received until Sept. 13 by Mordecai T. Endicott, Ch. Bureau of Yards & Docks, Navy Dept., Washington, D. C., for furnishing and installing 2 electric elevators at the Navy Yard, League Island.

Denver, Colo.—Bids are wanted Sept. 15 for installing steam heating plants in barrack buildings and officers' quarters at Ft. Logan. Address, Col. J. W. Pope, Ch. Q. M., Denver, Colo.

Annapolis, Md.—Bids will be received until Sept. 10 by Col. F. L. Denny, Q. M., U. S. Marine Corps, Washington, D. C., for furnishing material and constructing 1 commanding and 2 junior officers' quarters at Marine Barracks, Naval Academy, Annapolis.

San Francisco, Cal.—Bids are wanted Oct. 1 for dredging in San Pablo Bay, Cal. Address Lieut.-Col. W. H. Heuer, Corps Engrs., U. S. A.

Philadelphia, Pa.—Bids will be received at the office of the Light House Engr., Philadelphia, until Sept. 16 for furnishing material and erecting a lighthouse, an oil house, bat barn, etc., at the Reedy Island Front Light Station, Del., as advertised in The Engineering Record.

Philadelphia, Pa.—The following bids are stated to have been opened at the U. S. Engr. Office Aug. 21 for dredging Delaware River and constructing an artificial retaining bank; the contract calls for excavating and depositing 10,900,000 cu. yds. of material, and for 175,000 yds. of material placed in retaining banks: Maryland Dredging & Contracting Co., of Baltimore, 16 cts. and 90 cts. a cu. yd., total $1,901,500; Morris & Cummings Dredging Co., of New York, 14 4/10 cts. and 1.05 cts. a cu. yd., total $1,753,350; American Dredging Co., Philadelphia, 13 9/10 cts. and 48 cts. a cu. yd., total $1,559,100.

Bids were opened Aug. 25 at the U. S. Engr. Office for the construction of a timber bulkhead enclosed basin at Dan Baker and Stony Point Shoals. The lowest bid was $239,057 from Sanford & Brooks Co., of Baltimore, Md.

Buffalo, N. Y.—Maj. T. W. Symons, Corps of Engrs., U. S. A., writes that the lowest bid opened Aug. 22 for the hire of dredging plant for excavating in Niagara River and Tonawanda Harbor was from the Lake Erie Dredging Co., Buffalo, at $112 per day of 8 hours for each dredge and drill boat, including crew, tugs, scows, etc. There is $245,000 available, contract to run until this is used up, but not longer than Dec. 31, 1904.

Newport, Vt.—The following bids were opened Aug. 21 at the Treasury Dept., Washington, D. C., for the construction (except heating apparatus, electric wiring and conduits) of the U. S. Post Office, etc., at Newport, Vt.: Richardson & Burgess, Washington, $78,867; Conners & Brother, Lowell, Mass., $75,800; S. C. Moore & Son, Kokomo, Ind., $80,612; Congress Const. Co., Chicago, Ill., $83,843; Peter Keeler, Albany, N. Y., $91,696; A. B. Stannard, New York City, $78,000.

Memphis, Tenn.—Bids were opened Aug. 7 by Capt. E. E. Winslow, Corps of Engrs., U. S. A., and contracts have been awarded as follows: To Memphis Contracting Co., of Memphis, work in Reelfoot Dist., 150,000 cu. yds. at 12.40 cts. per cu. yd.; also work in Yazoo Levee Dist., 360,000 cu. yds. at 16.70 cts. per cu. yd.; to Anderson & Van Hook, of Helena, Ark., work in White River Dist., 60,000 cu. yds. at 15.85 cts.; to Geo. R. Lacy, of Arkansas City, Ark., work in White River Dist., 60,000 cu. yds. at 18.95 cts. Bids received at the same time on the following levee work were rejected and new bids for same will be opened Sept. 2: Work in White River Dist., including 90,000 yds. of enlargements near Helena, Ark., 160,000 yds. on beginning of the Modoc loop, and 50,000 yds. of construction at Ferguson.

Memphis, Tenn.—Bids were opened Aug. 20 by Capt. Chas. L. Potter, Corps of Engrs., U. S. A., for levee work in 3d Dist., Improving Mississippi River, and contracts were recommended for acceptance, as follows: To M. J. Rosch & Co., Memphis: Stations 3,100-3,125, 143,000 cu. yds.; Stations 3,125-3,156, 145,000 cu. yds.; Stations 3,156-3,189, 145,000 cu. yds., Stations 3,189-3,229, 145,000 cu. yds.; Stations 3,229-3,245, 147,000 cu. yds. all at 19.70 cts. per cu. yd. To Lawrence Bros., Wickliffe, Ky.: Stations 2,572-2,880, 60,000 cu. yds., at 16.50 cts.; Stations 3,800-3,942, 105,000 cu. yds. no bid recommended for award. To Israel R. Bobbet, Cofield, La.: Stations 4,670-4,725, 137,500 cu. yds., at 15.95 cts. per cu. yd.; Stations 4,725-4,780, 137,500 cu. yds., at 16.70 cts.; Stations 4780-4,924, 120,000 cu. yds., no bid recommended for award; Stations 4,887-5,230, 161,000 cu. yds., no bid recommended for award. All of above stations are in the Lower Yazoo Levee Dist. The following stations are all in Upper Tensas Levee Dist.: Stations 783-808, Arkansas River, 105,000 cu. yds., no bid recommended for award; Lewis & Jenkins, Memphis, Stations 2,252-2,533, 144,000 cu. yds., at 21.50 cts. per cu. yd. To M. L. Linnan, Lauderdale, La.: Stations, 3,950-4,080, 95,000 cu. yds., at 16 cts.; Stations, 190-256, 72,000 cu. yds., at 17.48 cts. To Donovan & Daily, Rougere, La.: Stations 4,080-4,210, 100,000 cu. yds. at 19.70 cts.

MISCELLANEOUS.

Osceola, Ark.—Asst. Engr. of St. Francis Levee Bd. John A. Fox writes that the contract, for dredging about 13 miles of drainage canal (223,000 cu. yds.) has been awarded to the Drainage & Improvement Co., of Kankakee, Ill., at 11½ cts. per cu. yd.

Philadelphia, Pa.—Local press reports state that bids are about to be asked by the Bureau of Surveys for dredging the channel of the Schuylkill River, southwest from Grays Ferry bridge. Estimated cost, $200,000.

Stockton, Cal.—The contract for constructing a concrete bulkhead along the water front, 200 ft., has been awarded to John Craven, of Stockton, at $25.47 per ft.

St. Ann's, N. S.—Bids are wanted Sept. 5 for constructing an extension to wharf at South Gut, St. Ann's. Fred Gelinas, Secy. Dept. Pub. Wks., Ottawa, Ont.; E. G. Millidge, Res. Engr., Antigonish, N. S.

Galveston, Tex.—Bids will be received by the Co. Comrs. until Sept. 6 (readvertisement) for constructing a seawall, 17,593 ft. in length, of concrete on a piling foundation with rip-rap protection. G. W. Boschke, Engr. in Charge, Galveston.

Co. Treas. J. S. Waters has secured the approval by Judge T. S. Johnson, office assistant Attorney General, of $500,000 seawall and breakwater bonds. This is the first batch of this issue of $1,500,000 bonds which will be presented to the Attorney General for approval.

NEW INDUSTRIAL PLANTS.

The Pennsylvania Malleable Co., 1119 Frick Bldg., Pittsburg, will spend $200,000 in improvements at McKees Rocks, Pa., which include a 120x300-ft. frame construction building for a daily capacity of 600 to 700 wheels and an addition of 300 H.-P. to power plant, for which boilers, engines and electrical equipment will be required.

The Portsmouth Cereal Co., Portsmouth, O., expects to erect in near future a 60x45-ft. building and a 45x42-ft. engine and boiler house.

The International Harvester Co., Deering, Chicago, Ill., is building a foundry and 5-story manufacturing building in which machinery is to be driven electrically from its central power station.

The Jeanesville Iron Works Co., Jeanesville, Pa., is about to build a plant at Hazleton, Pa., comprising 6 buildings, the main structure 106x538 ft. of steel frame and brick. The other buildings include a 2-story 50x74-ft. pattern shop, a 3-story 50x202-ft. pattern storage, a 47x87-ft. power house, a 3-story 60x65-ft. office building and a 2-story stable, all of brick, with slate roofs. Machinery will be electrically driven, there will be 5 to 20-ton electric cranes, the main building will be heated by blower system and there will be 3 cupolas in foundry. Hales & Ballinger, 12th and Chestnut Sts., Philadelphia, are architects and engineers.

The Cocheco Mfg. Co., Dover, N. H., is putting up a 230x70-ft. power station in which a 10,000-H.-P. boiler plant will be installed. The boiler specifications are not yet finished.

BUSINESS NOTES.

The York Manufacturing Co., York, Pa., reports the following contracts recently placed: Orange, Tex., Light, Ice & Water Wks. Co., 35-ton ice-making plant; Eastern Kentucky Asylum for Insane, Lexington, Ky., 10-ton plant; Allegheny, Pa., County Morgue, 7½-ton plant; Rock Island, Ill., Plow Co., 20-ton plant for tempering vats; Ideal Cocoa & Chocolate Co., Lititz, Pa., 7½-ton plant; Meridian, Miss., Ice Co., 50-ton plant; People Pure Ice Co., Muncie, Ind., 30-ton plant; Washington, D. C., Market Co., 20-ton freezing and distilling system.

The C. O. Bartlett & Snow Co. has been incorporated, succeeding C. O. Bartlett & Co., and its plant for building mill, paint, conveying and elevating machinery and steam and direct heat dryers is located on its own property bounded by French, German, Winter and Falls Sts., Cleveland, O.

The Westinghouse Electric & Manufacturing Company has removed its district office from the Sun Building, Washington, D. C., to the Continental Trust Building, Baltimore, Md.; this move being made on account of the large amount of business which that company transacts in Baltimore.

The Pittsburg Valve & Fittings Co. has placed a contract with the Westinghouse Electric & Mfg. Co. for the electrical equipment of its new works at Barberton, O.

Mr. Wm. J. Martin, of the mechanical department of the Geo. A. Fuller Co., 137 Broadway, New York City, wishes to receive catalogues of every description for office files, reference and ordering.

An engine built by the Ball Engine Co., Erie, Pa., is being installed in the tobacco factory of R. & W. Jenkinson, Pittsburg, for electric lighting.

The Jessop Steel Co., of England, has recently purchased direct current apparatus from the Westinghouse Electric & Mfg. Co. for electric power distribution in a large steel plant it is erecting at Washington, Pa.

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Shop Tests of Engines of Moderate Size.

While it is probable that in these busy times purchasers of steam engines are more concerned in having them shipped and put in operation promptly than they are in the amounts of steam they will use under various conditions imposed by service, yet many, doubtless, will be interested in reading, in an abstract of one of the selected papers of the Institution of Civil Engineers, printed on another page, the careful manner in which it is evident that engines are tested by one of the largest firms in Great Britain before they are shipped from the works. The paper in question, by Mr. E. H. Rayner, states that this practice of testing has been caused by the exacting requirements of engineers as regards the economy of an electric generating plant, and brings out the fact that builders obtain many data useful in future orders, and that they are able to effect improvements which would hardly be possible unless the tests were made. Of course tests as usually made are costly and take much time, and to reduce this the builders have devised quick and accurate methods. A plant has been installed for supplying steam, for condensing it, and for weighing it after it is condensed, also for measuring the electric current, and thus determining the load. By weighing the steam condensed the consumption can be obtained in a few minutes where it would take almost as many hours if the steam were measured by weighing the water fed to the boilers. The author states that it would be the work of several days to obtain satisfactory results by weighing the feed water supplied the boilers when testing engines at full, three-quarter, half and quarter load, both condensing and non-condensing, such as can be obtained with the adopted method between breakfast and dinner hour. Not the least important feature of this practice is that it gives data which enable one to proportion an engine properly for a given service so that it will develop power with the least expenditure of fuel. The tests also show if the valves are set properly and insure that piston and valve leakage or abnormal friction is discovered and corrected before the engines leave the shop.

This practice is in striking contrast with that in the United States, where few builders are equipped for making such tests, although it is the custom of all builders of small engines to at least run them under full load for a period sufficient to set the valves and see that they run properly. A few have facilities for testing the water consumption, but this even is difficult with direct-connected generating sets, as the generators are seldom sent to the shops of the engine builders as seems to be the practice in Great Britain, and it is inconvenient to secure full load by means of a brake for any but small engines. Tests made after an engine is installed are so costly and difficult, if not impossible, to make that they are almost invariably omitted. It is to be regretted when specifications for engines, particularly those of the compound high rotative speed type, call for guarantees as to the steam consumption, that tests are not made in each instance to see if the guarantee is fulfilled. Not that the difference of a pound or two in the steam consumption of an engine of small power will make a very material difference to the owner, but such saving in almost any engine would be sufficient to cover a good deal more than the cost of a test in a short time and the test would show any abnormal conditions affecting adversely the economy of the engine. Of course if these tests are made the purchaser will have to pay for them, either in the first cost of the engine or by agreement to do so. He can undoubtedly well afford to do so in most instances on account of the better operating engine that will be secured.

It is proper to mention at this time another matter regarding engine tests made under different loads that seems to be neglected in the tests described in the paper and is usually ignored in tests. It should not be forgotten that there are two points that it is important to know in an engine. One is its most economical load, or, to put it in another way, the load under which an engine will operate with the lowest possible steam consumption per horse power per hour. The second is the maximum load that it will operate under continuously without too great a reduction in speed. The speed requirement is of importance in electric driving. The economy at the "rated load" means little or nothing, for the rated loads of engines of the same cylinder size and rotative speeds vary considerably with different builders, as will be seen by anyone that will take the trouble to compare their catalogues. In all steam-consumption tests made at different loads, the load should be increased sufficiently above the load of lowest steam consumption per unit of power developed, as shown by the test, to determine what this most economical load is. This is easily obtained, as the steam consumption per unit of power developed increases with an increase or decrease in load above or below that which is the most economical one. Furthermore the load should be increased up to the maximum horse power of the engine, not so much to determine the steam consumption as to find out how much work the engine can do. Data on the former point are useful in proportioning cylinders and data on the latter enable one to know in advance how much power can be obtained from an engine—particularly useful information when it is to be used in electric service. This kind of data on compound engines is sadly lacking. Information upon both of these points, not only with compound engines but engines of all types, is much more valuable than the number of pounds and fractional parts of a pound of steam that an engine uses in operating at some load much less than the average that it is designed for.

The Engineering Legacy of Victor Hugo.

Years ago Victor Hugo wrote in "Les Misérables" a fanciful essay on the sewerage system of Paris. It is a vivid literary work, and, even in the average poor translation, it pictures the great conduits and their streams of filthy water so forcibly that to-day, years after the author's death, the Paris sewers are probably regarded by most people of moderate education as among the wonders of the world. In one part of this essay, to use a name fitting such a digression from the story he was telling, Hugo bewails the unintelligent waste of the flood of sewage, which was passing into and polluting the Seine instead of renewing the fertility of the fields about the city. His computation showed that the authorities were stupidly allowing fertilizing materials worth enormous sums to be entirely wasted, and his arraignment of such a policy remains a model of sarcasm to writers for newspapers.

The only unfortunate feature of the matter is the fact that the great Frenchman was not confining his attention to actual conditions and to scientific truths, for his seeming knowledge was as much a fiction as the adventures of the oppressed Valjean. But such was his convincing clearness of style and so great his skill in the marshalling of alleged facts, that ever since his time men of letters have felt called upon to pose as authorities on sewage disposal. Inasmuch as a literary fellow reaches an audience far larger than his humble scientific brother can expect to gain, and he tells his tale with a grace hopeless of attainment when coupled with mathematical formulas and chemical equations, his engineering influence is decidedly for the bad. That this is so, the following extract from a Hugo-inspired editorial in a Brooklyn paper of great influence bears ample witness: "The truth is that the present system of sewering is radically wrong and abominably wasteful. We are throwing away in the waste of the cities materials for which the land may one day starve; indeed, many acres of farm land already show the effect of hunger and no longer produce the crops they yielded to the first tillers. Even on the prairies, where it was supposed that the soil would require no fertilizing for a century to come, the farmers are buying bone dust, guano and the compounds of Barren Island, yet every town is casting away phosphates and nitrates that would satisfy the craving of the emptiest soils and make the brown earth green again."

The lack of information such a statement indicated is equalled only by the evident good intentions of the writer, yet good intentions proverbially pave the place where the spread of such fairy tales puts the unfortunate engineer. His scientific knowledge is placed at naught by the chimera of a French novelist, and one of the most difficult problems of municipal engineering and applied chemistry is settled with a few strokes of a pen. The absurdity of the statements in the above quotation is evident from the fact that the investigations of Dr. Nichols and other eminent chemists have shown the fertilizing materials in a ton of sewage to be worth only from one to four cents. It costs four times as much to prepare a farm for sewage irrigation as it does for ordinary agricultural methods, and when the land is ready the cost of management is much raised by the presence of the sewage, while the returns are restricted by the limited number of crops which can be profitably grown with sewage irrigation. Except with dry climates or very sandy soil where the land needs water, sewage is a hindrance rather than an advantage, and if fertilizers are required the wisest course to pursue is to purchase them from manufacturers who supply a material far better for the land than a flood of stinking water. This is truth, resting on facts demonstrated by able scientific investigators. The quotation from the "Brooklyn Eagle" is merely graceful, well-meant untruth.

The evil effect of such statements in influential journals is evident from the facts in the present case. The quotation is from an article attacking the system of sewage disposal designed for the Passaic River valley in New Jersey by Messrs. Rudolph Hering, Wm. M. Brown and J. J. R. Croes. These men have spent a lifetime gathering information from all sources which will be of use in solving just such problems as the drainage of this valley presents. They have available in their libraries all the data which the agricultural chemists can supply concerning the fertilizing value of sewage, and if they decide from their knowledge and experience that it is better for the taxpayers along the Passaic for the sewage of the valley to be discharged into New York harbor than to be spread overland, it is hardly in the line of good public policy for their decision to be so oracularly overturned. They are all men of international reputation for the value of their knowledge on the subject, and it is not in keeping with its usual sound sense for the journal named to question their mature judgment so flippantly and on such ridiculous grounds. The towns and cities in the Passaic Valley are already in conflict over the sewerage system recommended by these engineers, but the controversy is over financial and not engineering subjects. The disposal of the sewage in New York Harbor, as proposed, will cause no trouble, no inconvenience, no nuisance; investigations of tidal flow and channels have settled that question and rendered needless any apprehension on that score among the people on the Brooklyn shore of the harbor. All these facts could have been readily learned by the "Eagle" had it cared for facts.

The Use of a Sand Box under the foot of a column which is to be lowered slowly has been proved to be very old by recent discoveries in Egypt, mentioned by Mr. Ludwig Borchardt in the "Centralblatt der Bauverwaltung." Three similar tombs were found near the pyramid of Onnos, all dating from about 500 B. C., and one ready for the interment of a mummy. It was a chamber about 17 feet long, 9 feet wide and 10 feet high to the crown of the arched roof of large cut stones, the first stone arch of the kind on record. The sarcophagus was in place and over it was the heavy limestone cover slab which was to be lowered when the mummy was in position. This stone was 13 feet long, 3 feet thick and just a trifle narrower than the tomb chamber. It was upheld by six rough pillars of inferior workmanship to the other masonry and evidently temporary, and had two massive tenons on each side, fitting in vertical slots or niches in the walls. These niches were carried down about 6½ feet below the floor of the chamber and in them would be placed sand to support wooden posts on which the weight of the slab, about 17 tons, would come when the temporary masonry pillars were removed. Between the two niches on each side of the chamber a pit was excavated large enough to hold a man, and the niches had openings at different elevations connecting with this pit. When it was time to lower the stone, it would only be necessary to have a man enter each pit and open these passages one after the other in order to allow the sand to escape and the timber posts to settle slowly. Such posts were found in the niches of the two tombs containing mummies. When the slab was in place the men could crawl over it and thus leave the chamber.

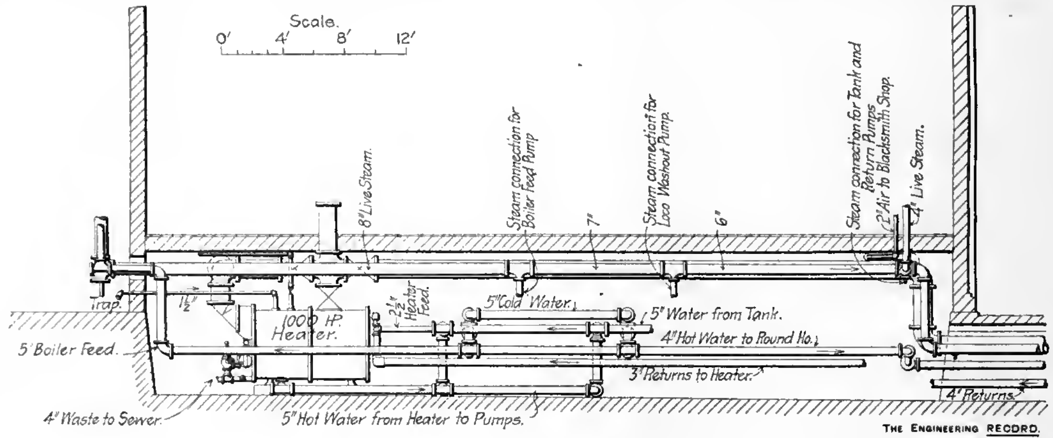
Power, Lighting and Heating at the Du Bois Shops of the Buffalo, Rochester & Pittsburg Ry.

The Buffalo, Rochester & Pittsburg Railway has recently completed a new colony of locomotive shops at Du Bois, Pa., for which the electric and compressed air system of power transmission was adopted, with power, lighting, compressed air and heating all served from a central station. A power plant, designed on modern lines, has been provided for this work with underground tunnels or subways connecting power station and the various buildings. For warming, the fan system of circulating heated air is used.

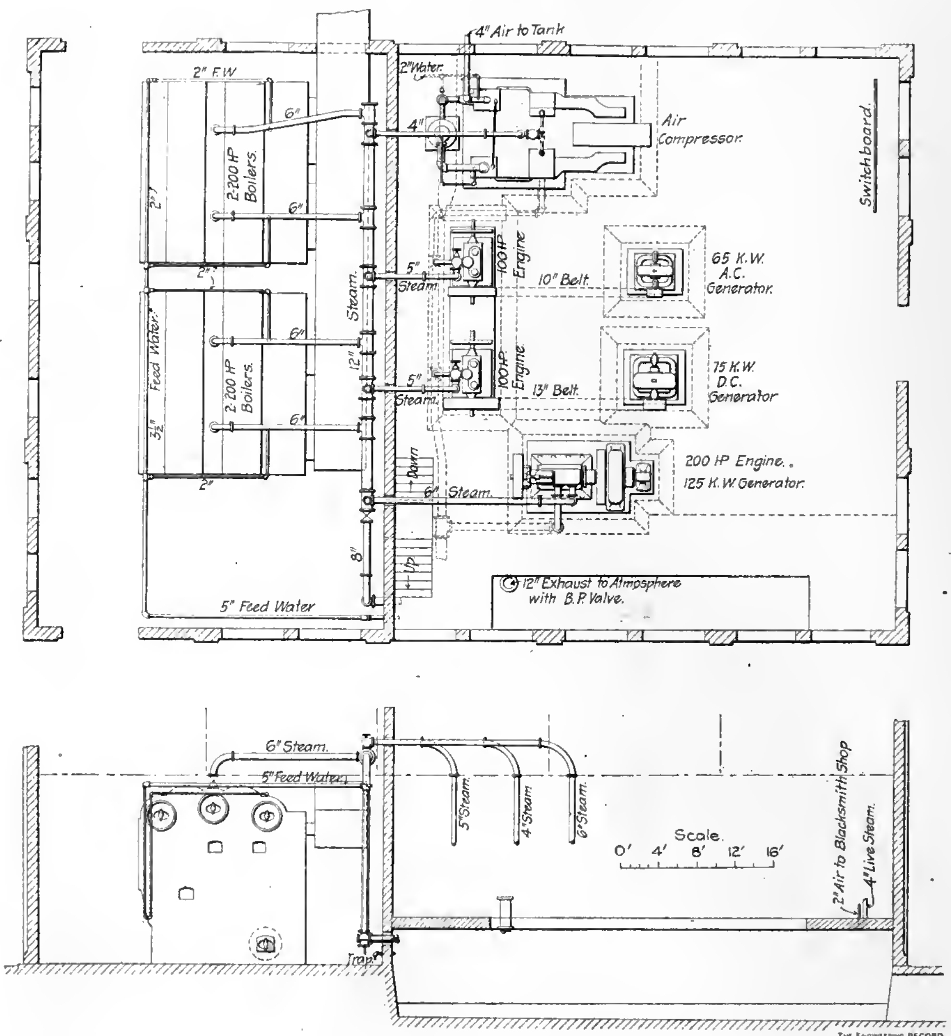
The Du Bois shops, for which 32 acres of land were available for both shop plant and yard, are planned to handle the repairs on about 150 locomotives with provision for expansion for five years, or for 75 engines final increase, making a total of about 17 engines per month. The shops include a main building 134x524 feet in plan, comprising the machine, boiler and tank shops, a blacksmith shop 80x142 feet, the power house 63x93 feet, an office and storehouse 60x120 feet and in addition to these a 30x60-foot oil house, a 16-stall roundhouse and a 26x140-foot coal, coke and bar iron storage.

The power house is of brick with a steel truss roof, the walls 13 inches thick with 17-inch pilasters. It is of the class with boiler and engine rooms side by side, separated by a 12-inch brick wall; the boiler room is 37 feet in width and the engine room 54 feet. The engine-room floor is as usual in this type of plant at a higher level than that of the boiler room and a basement is provided underneath for pumps, heater and incidental apparatus, piping and electric feeders. The building is connected through the locomotive shop to the roundhouse by a 5 feet x 4 feet 7-inch brick and concrete subway, which is drained to a sump at the roundhouse end. A plan and cross-sectional elevation of the power house and an elevation of the piping at one end of the power house basement are given in the accompanying drawings.

The boiler equipment comprises four 200-



PIPING IN THE POWER HOUSE BASEMENT.



PLAN AND CROSS-SECTION OF THE POWER HOUSE.

horse-power Stirling water-tube boilers, set in two batteries, and provision has been made for an additional 200 horse-power boiler. The boilers are hand fired and the coal is received on a trestle alongside the boiler room and delivered through the wall by gravity. For draft a 120-foot brick stack, 6.5 feet in inside diameter, is provided, located outside the building. It rests on a concrete foundation 14.5 feet square and has an outside diameter of 14.5 feet, tapering with a batter of ¼ inch in 12 inches to a diameter of 9 feet 4 inches at the top. Each boiler has a separate steam connection to the steam header with a stop valve close to the boiler. The header is located overhead in the boiler room, and branch pipes to the machinery in the engine room pass through the partition wall into the engine room with an angle valve in each case at the header.

The equipment of the engine room includes one direct-connected electric generating set of 125 kilowatts capacity for power and day lighting and two belted generators, one for lighting shops at night and furnishing such power as required, and the other for yard and distant lighting for which alternating current distribution was adopted. These units are all of the Westinghouse manufacture, the direct-connected set consisting of a 14 and 24x14-inch compound engine and a 250-volt 125-kilowatt engine-type generator driven at 280 revolutions per minute. The belted machines are each driven by a 12x11-inch standard engine, the direct-current machine being of 75 kilowatts capacity, at a speed of 750 revolutions per minute, and the alternating-current machine of 65 kilowatts capacity, giving two-phase current at 2,200 volts and 7,200 alternations per minute at a speed of 900 revolutions. Besides the electrical machinery there is a steam actuated Ingersoll-Sergeant air compressor with a capacity of 950 cubic feet of free air per minute. It has 14x18-inch duplex steam cylinders and compound double-acting air cylinders 14¼ and 22¼ x18 inches in size.

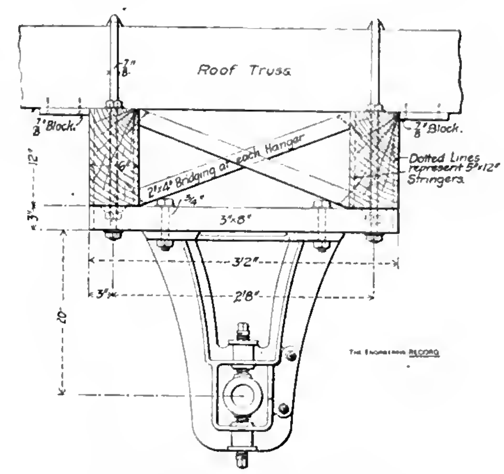
The exhaust from the steam machinery is collected by a system of pipes running under the engine room floor in the basement, where at one end is located a feed water heater and various pumps, as shown in an elevation referred to. Ordinarily all the steam is passed through the heater, which is a 1,000-horse-power Cochrane open-type heater and thence is carried in a main 12 inches in diameter to the shops where it can be utilized for heating. The heater can be by-passed when desired and provision is also made at the heater for surplus exhaust steam to pass to the atmosphere, the out-board exhaust pipe being fitted in the usual way with a back pressure valve so that steam is only allowed to go to waste when the supply of it exceeds the demand. The boiler feed, return and locomotive wash-out pumps are arranged in line with the feed-water heater, though not shown on the drawing. The return pump discharges water of condensation from the heating system to the feed-water heater, the condensation being delivered to a return tank from the subway mains; and the boiler feed pump draws from the feed-water heater and delivers to the boilers. The pump for supplying water to the locomotive shop for washing out locomotive boilers is interchangeable with the boiler feed pump. The pumps are all of the Worthington type.

The switchboard, in the engine room, is of the Westinghouse pattern, of white Italian marble, 28 feet long and 8 feet high. The panels at one end contain the controlling apparatus for the alternator with plunger switches, one per phase and each leg fused with porcelain tubular enclosed fuses on the back of the board. The panels at the other end contain the instruments and switches for the motor feeder circuits, which are ordinarily fed from the 125-kilowatt direct-current generator; and in between are the panels for the 75-kilowatt direct-current machine and instruments for the lighting circuits. There are two sets of direct-current bus bars, one for light and the other for power, and either generator may be operated on either or both, or both machines on either light or power.

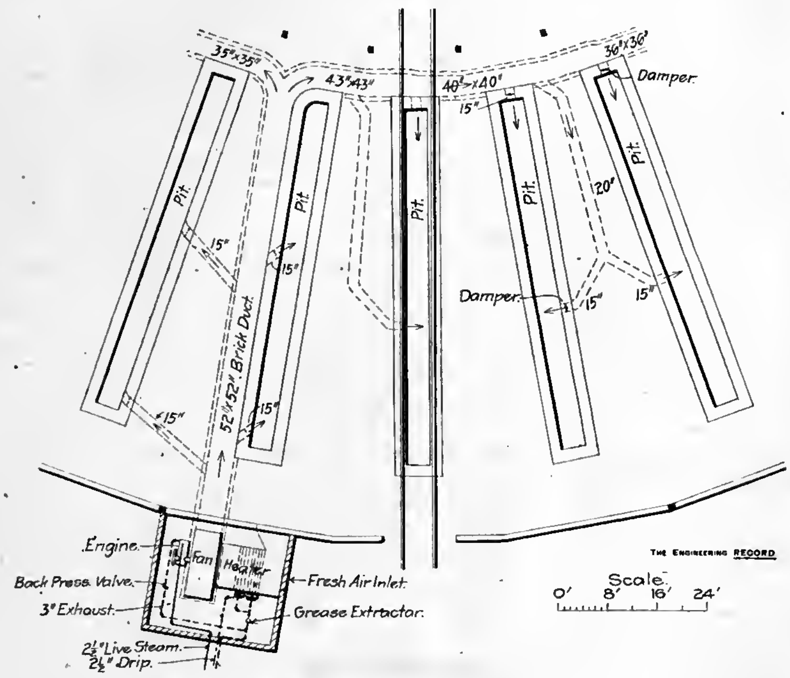
The electric feeders encased in wrought-iron pipes are carried in the subway to the buildings, as explained. For power work the group system was adopted with line shafts attached to the roof trusses of the machine shop bays. The shafting hangers are suspended from stringers, which were attached to the trusses by means of U-bolts, to avoid weakening the truss timbers by any boring or cutting. An accompanying detail drawing will serve to show the general design of the hanger supports. The line shafts are carried on Hyatt roller bearings. Five motors drive the machine shop, the largest of 40 horse-power. Altogether there are about 160 horse-power in motors in the shops, supported in general on platforms elevated about 6 feet above the floor. In addition there are two 50-ton Shaw electric traveling cranes in the machine shop, each with a 6-ton auxiliary hoist; the cranes have a span of 68 feet and a travel of 520 feet or more. The main hoist has a speed of 6 feet per minute, the trolley, of 100 feet per minute and the bridge, of 250 feet. The feeders for these motors as well as the lighting circuits, are controlled from a distributing panel in the locomotive shop.

The artificial illumination of the machine shop is effected by three rows of arc lamps, nine in each row at 60-foot centers. One of these is at the center of the building and the others are under the crane runways. In addition each machine and bench has one or more 16-candle-power incandescent lamps. In the blacksmith shop there are three circuits for incandescent lamps and eight long-burning arc lamps. Each circuit has usually 20 incandescent lamps, which are of the 230-volt type. Each arc lamp is controlled by a separate switch. The outside lighting comprises three miles of conductor with lamps spaced 400 feet apart. The lamps are connected on three circuits of 25 lamps each and are of the Manhattan alternating-current series enclosed long-burning type. The alternating system also includes a fourth circuit which feeds incandescent lamps on 104-volt circuits at distant points, transformers being installed at the points of use to effect the required drop in voltage. The outside arc circuits are connected in series with a Manhattan series alternating-current voltage regulator.

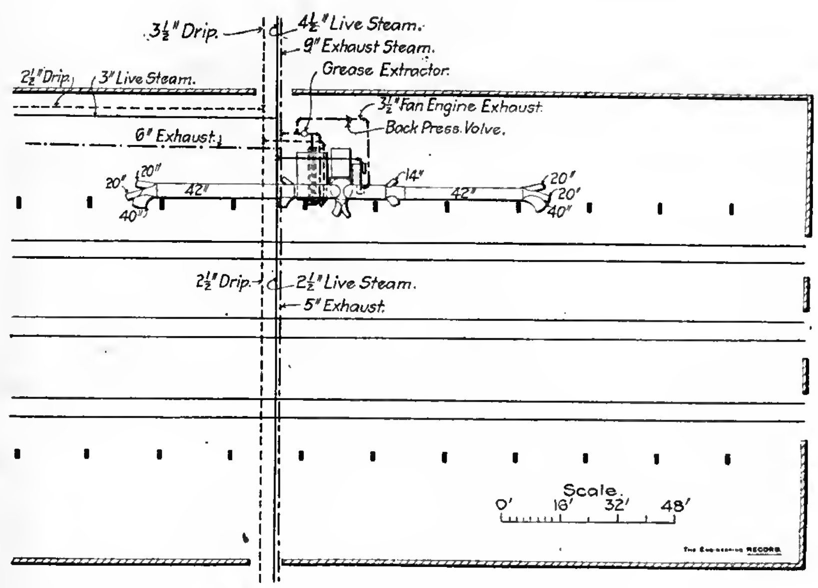
Compressed air is used in the hoists on the various jib cranes, nineteen of which were built by the Whitney Foundry Equipment Company, of Harvey, Ill., in the portable drills, riveters, hammers and jacks; in oil house for raising the oil from basement to the floor above; also in roundhouse drop pits. The first floor of the oil



Support for Shaft Hangers.



Method of Heating Round House.



One of the Two Fan-Heater Units in Main Shop.

house has a clear headroom of 12 feet 10 inches, is 4 feet above the tracks and there is an 8-foot basement. The building is divided into two sections by means of a 12-inch firewall. One section is used as a distributing room and contains shelving for the storing of portable equipment removed from engines. The other section is used for storing oil and waste. The basement contains the tanks. The oil flows from large tanks to smaller tanks through a check valve, and the smaller tanks are emptied by air pressure.

The method of warming the buildings is indicated in the accompanying part plans of the apparatus in the machine or locomotive shop and of that in the roundhouse. The main portion of the machine shop measures 38 feet to the roof truss and there are two lateral extensions each measuring 20 feet to the roof truss. The total cubic contents of the building is 2,440,000 cubic feet. Half way between one end and the middle of the building, each placed in the same side extension, are two duplicate fan units, these being 170-inch three-quarter housing up-blast Buffalo steel-plate fans of the exhauster type. They have 10-foot blast wheels direct connected to 9½x10-inch single horizontal center-crank Buffalo engines, capable of driving them at a speed of 175 revolutions per minute. The speed at which they are designed to run is 150 revolutions per minute, delivering 59,000 cubic feet of air per minute at a pressure of three-quarters of an ounce per square inch.

Each fan draws the air through a heater composed of eight sections of steam coils in series. These sections or coils consist, each, of two staggered rows of 1-inch wrought-iron pipe screwed into the usual sectional cast-iron base or header. From the fan the air is blown directly upward through a 72-inch pipe to a point above the roof truss where the pipes divide into two smaller branches each 50 feet long. From these branches the air is blown through outlets at a velocity of 1,200 feet per minute outward in all directions and downward at an angle of 35 degrees. The farthest distance the air is blown is 120 feet. The air supply is taken directly from the building, the assumption being that sufficient ventilation is provided by the numerous windows and doors.

The steam used during the day time is entirely the exhaust from the fan engines and that from the engines in the power house. A grease extractor is placed in the exhaust pipe leading to the heater, so that the exhaust steam from either source has first to pass through the extractor before reaching the heater. All the condensation is returned to the power house for delivery to the boilers. The combined apparatus is designed to warm the building in every part to a temperature of 65 degrees when the outside temperature is 15 degrees below zero.

The scheme of air circulation is as follows. The current of heated air leaving the outlets at a high velocity, but far above the heads of the workingmen spreads out and diffuses, returning by a gentle flow along the floor from all parts of the shop toward the apparatus. The heating installation is designed to produce a 20-minute air change, that is, once in every 20 minutes the entire air in the building is designed to pass through the heater and be re-distributed. The temperature of the discharge is allowed a maximum of 160 degrees Fahrenheit.

The warming of the roundhouse is also accomplished by the hot-blast system, the use of radiating coils in the pits being discarded on the grounds of being slow to heat up the space to be warmed and of offering great inconvenience to the men working under the engine. The roundhouse has at present 16 pits each 60 feet long, and its total cubic capacity is 912,000 cubic feet. The fan unit is located just outside the building proper. The heater consists of eight separate sections each 7 feet wide by 8 feet 10 inches high. The air is exhausted from the building through the steam coils by means of a 140-inch three-quarter housing, bottom horizontal discharge, Buffalo fan, direct connected to an 8x8-inch horizontal center-crank Buffalo engine. The blast wheel is 99 inches in diameter and is driven under ordinary conditions at a speed of 200 revolutions per minute, giving a blast density of approximately ¾ ounce per square inch. The air is conveyed to the farther side of the building at about 2,000 feet per minute through an underground brick duct, which divides into two branches passing along the ends of the pits. From these a 15-inch tile branch enters at the end of each pit, while between each pair of pits a 20-inch tile branch is carried, supplying two 15-inch branches blowing it at the sides of the pits. A volume regulating damper is placed in each branch. The tile piping and brick ducts are laid in Portland cement. The bottom of the brick ducts has a slope of ⅛ inch per foot for drainage in case of a leak. The heater also utilizes exhaust steam, and an oil separator is used and the condensation returned to the power house.

The shops were designed under the supervision of Mr. R. H. Soule, as consulting engineer, by Mr. J. M. Floesch, chief engineer of the Buffalo, Rochester & Pittsburg Railway, and Mr. C. E. Turner, superintendent of motive power. The details of the mechanical equipment were placed in charge of Mr. W. R. Maurer, chief draftsman of the motive-power department. The steel work of the buildings was furnished by the American Bridge Company; the brick work by Mr. Hiram H. Edgerton, of Rochester, N. Y.; the piping by Messrs. Howe & Bassett, of Rochester; the electric wiring by the Higgins-Almstead Company, of Rochester; and the heating apparatus, together with an extensive installation of down-draft forges for the blacksmith shop, was designed and installed by the Buffalo Forge Company, of Buffalo.

The Steam Plant of the Carpenter Steel Company, Reading, Pa.

About a year ago the Carpenter Steel Company built at Reading, Pa., a 1,200-horse-power steam plant to run two rolling mill engines, to supply water under pressure for several hydraulic rams and presses and to provide for other necessities about the plant. The company's property borders the Schuylkill River where that stream is utilized as a portion of the Schuylkill Navigation Company's canal, and occupies a bluff about 25 feet above the tow path. The steam plant was located on the bank of the river so that the water could be availed of for condensing purposes and the rocky bank was blasted away to make room for the building. Vertical boilers were installed, so that comparatively little ground area was required for the steam plant, and although the building was carried upward sufficiently high to permit the withdrawal of boiler tubes, the building from the general ground level of the steel works appears to be quite low. The railroad tracks being at the works' level, the provision of coal bunkers was comparatively easy to make. In connection with the collection of steam from the boilers and the delivery of feed water to them, an interesting system of piping has been evolved.

The boiler house is 38x56 feet in plan and is of brick construction with a steel truss roof carrying a monitor 53 feet above the boiler room floor and with windows on all sides. Six boilers are at present in place, but as indicated in the accompanying plans, the building can be extended from one end and additional boilers added. The various pumps are placed in a separate room adjoining the boiler room at the floor level of the latter, but the pump room does not extend above the yard level. Its roof supports the yard and consists of expanded-metal concrete arches designed to carry 500 pounds per square foot. The coal pockets are located along the inner wall of the boiler house, between that wall and a substantial retaining wall supporting the yard. There are three pockets, one for each pair of boilers, and they are provided with bottoms floored with concrete and sloped to deliver through openings in the boiler house wall, one opening opposite each boiler. The coal cars are run over the pockets and dump directly into them, their total capacity being about 125 tons.

The boilers are of the Manning type, built by The Bigelow Company, of New Haven, Conn. Each is 74 inches in diameter and 24 feet 9 inches high, and is rated at 250 horse-power. In each boiler there are 284 tubes 2½ inches in diameter and 15 feet long, and a furnace 84 inches in inside diameter. The total heating surface in tubes in each boiler is 2,030 square feet and the total water and superheating surface, 2,888 square feet. The boilers are hand fired and bituminous coal is used; 150 pounds steam pressure is ordinarily carried. Each pair of boilers is served by a single self-supporting steel stack, 6 feet in diameter and 65 feet high, bringing the top about 75 feet above the grates. The area of each boiler smoke outlet from the boiler is 8 square feet, while the gross area of the stack is 19 square feet. The stack rests on a cast-iron ring base plate and is provided at that point with a 6x4x½-inch stiffening angle bar riveted to the inside. The anchor bolts, of which there are four, in each case, pull at their bottom against a grillage of four 20-pound channel bars.

Each boiler has a 7-inch steam outlet and the 7-inch pipe is turned upward in a long sweeping curve to a 16-inch header, into which it enters at the bottom. Each boiler connection has two stop valves, one at the boiler and the other at the header and between the first valve and the boiler outlet is a safety valve. While the use of two valves tends toward a doubly tight connection between boiler and header, the valve at the boiler is provided with a drain, in case water should collect above it. Expansion of the header is allowed for by the sweep connections, and the header being nearly 12 feet above the general yard grade was continued horizontally into the mill, as a main for the supply of the steam engines, pitching slightly, however, to provide for a flow of the condensation occurring within it in the direction of steam flow. The pipe joints were made with Merwith metallic gaskets.

For the supply of the pumps a 7-inch pipe taps the header in the boiler room. It starts in a long upward sweep from the top of the header before dropping to the pumps, to avoid carrying water to their steam cylinders, it being undesirable to attempt to make this connection in the outside run of the header between boiler house and mill building, and to allow furthermore of cutting out the steam main to the engines without shutting off the supply to the pump room. In the case of the steam engines, De Rycke separators are inserted in the branch live steam supply pipes.

The pumping equipment consists of a Blake twin pump and jet condenser, two boiler feed pumps, a tank pump, a pressure pump and two heaters in connection with the utilization of exhaust steam for heating the feed water. The primary heater is located at the entrance of the exhaust main into the pump room and is of the National type. The condenser employs a 12x30x18-inch twin vertical air pump.

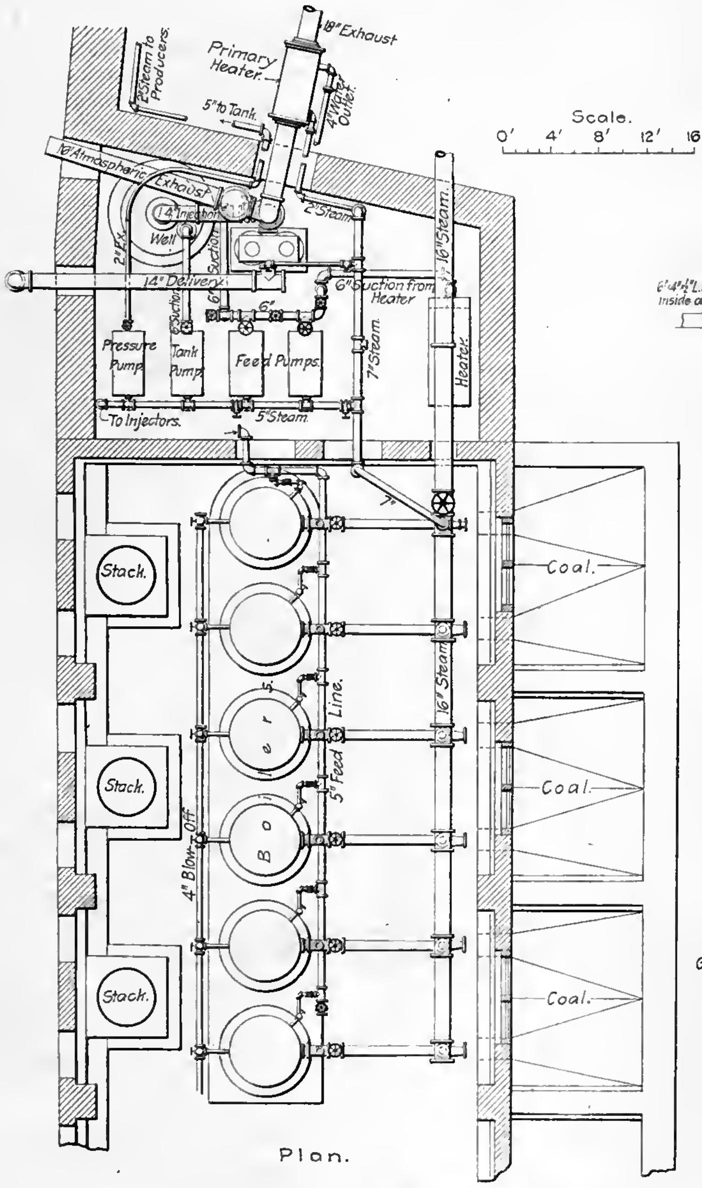
The pump draws from a well built below the pump room and filled by a 14-inch pipe from the river. Both injection and delivery pipes of the condenser are 14 inches in diameter.

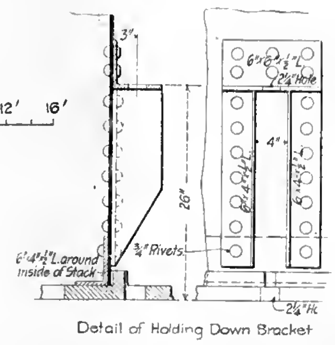
For the delivery of feed water, there is, as stated, a duplicate installation of feed pumps, and there are also a pair of Eynon & Korting injectors in the pump room, as a relay to the pumps. The pumps are arranged so that either one may draw from the auxiliary feed-water heater, which is of the open type, and then deliver to the boiler feed main, while the other draws what fresh feed water is necessary from the condenser injection pipe and pumps it either through or around the primary heater, according as to whether that heater is in commission or not, and thence into the open heater, from which it is taken by the pump mentioned and passed into the boiler feed main. The open heater is of the Cochrane type built by the Harrison Safety Boiler Works, of Philadelphia, and has a rating of 2,000 horse-power.

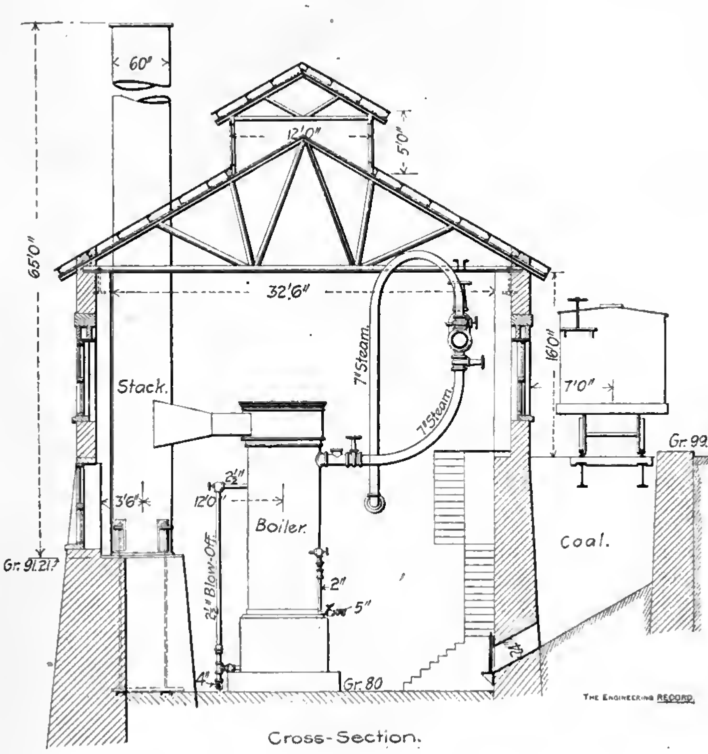
The feed water being drawn from the injection pipe is thus obtained from the river, and it was found that a water purifying plant would be desirable. For this work, duplicate installation of the Bachman purification system, controlled by Messrs. D. W. and R. P. Patterson, of Philadelphia, was made in the boiler room, occupying the spaces between the chimney bases. The feed water on the way to the boilers is passed through this apparatus, which comprises two filters and four chemical tanks. The feed main extends across the fronts of the boilers and the manner of taking off the individual boiler supplies to provide for expansion and contraction is indicated in the accompanying drawings.

The tank pump has a separate suction from the intake well and delivers to a 12,000-gallon tank in the mill building 50 feet above the floor line, for cooling purposes. When the injectors for boiler feeding are used, the water is taken from the delivery pipe of the tank pump. The pressure system for different rams and presses likewise takes its suction from the delivery of the tank pump. The boiler feed pumps are 10x7x10 inches in cylinder dimensions and the tank pump, 10x8½x10 inches, all of the Barr make; and the pressure pump is a Buffalo 7½x4x8-inch pump, and is controlled by a governor to maintain a pressure of 300 pounds for the hydraulic system, which includes a weighted accumulator.

The plant was designed by the E. G. Spilsbury Engineering Company, of New York City, the details of the work being laid out by Mr. George A. Mayland, of that company.







THE STEAM PLANT OF THE CARPENTER STEEL CO., READING, PA.

Economy Derived From Reheating Compressed Air.

The following is an account, reprinted from the "American Engineer," of tests performed by Messrs. W. G. Edmondson and E. L. Walker, students in the Railway Engineering Department of Cornell University, to ascertain the magnitude of the gain derived from reheating compressed air for use in small motors, with the idea that some such method could be advantageously put into application in connection with the use of compressed air in railroad shops, mines, etc., where compressed air is extensively used.

A small 2-horse-power vertical engine with a shaft governor was used as the motor. The compressed air coming from the compressor was first passed through a meter, and then before being admitted to the engine was passed through a reheater.

The amount of air used in each run was recorded by the meter, which was furnished for the test by the Equitable Meter Company of Pittsburg. The meter was especially designed to withstand high pressures and the air passed through it at the temperature of the atmosphere. The meter was calibrated for the pressures used in the experiments, before and after the runs were made, and the meter readings were then corrected from this calibration.

The reheater was constructed of three lengths of 1¼-inch wrought-iron pipe, which was surrounded by an outer casing of 6-inch pipe. This casing was also covered with an asbestos non-conducting covering to prevent the escape of heat. Gas was used as the fuel, and was burned in a burner placed at the base of the reheater. Gas was selected on account of the ease with which the supply of heat could be governed. A gas meter recorded the amount of gas used in each run, so that the amount of heat supplied to the reheater could be easily computed when the heat value per cubic foot and the number of cubic feet of gas supplied per hour were known. The engine was equipped with a prony brake, and an indicator was attached to the cylinder, which allowed both the brake-horse-power and the indicated-horse-power to be computed. In every case the temperature of the air was taken at the meter, and again after it had passed through the reheater, at a point as near to its entrance to the engine as possible.

In conducting the experiments three series of runs were taken as follows: Series I.—In which six runs were made, all at about 57 pounds gauge pressure, while the temperature of the air entering the engine was varied from 60 degrees Fahr. to 401 degrees. Series II.—In which five runs were made, all at about 82 pounds gauge pressure, while the temperature of the air entering the engine was varied from

60 degrees to 395 degrees. Series III.—In which two runs were made, at about 77 pounds gauge pressure, and the temperature of the entering air 42 degrees and 266 degrees respectively.

The average results from each run were then taken from the log of each run and are shown on the general result sheets, one of which is reproduced. The tests were performed during the month of April, 1902, in the Mechanical Laboratory of Sibley College, Cornell University. The term cubic feet of free air is used to represent the volume of air at standard conditions, which are taken in this case to be at a pressure of 14.7 pounds absolute, and at a temperature of 60 degrees Fahr.

Results and Conclusions.—The net gain in economy obtained with the lower pressure was 38.4 per cent., while with the higher pressure it was but 31.7 per cent. under the same conditions. In other words, a reduction of 31 to 38 per cent. in the cost of the production of compressed air for a plant by reheating the air from 60 to 400 degrees Fahr. before using it.

The curves in Figure 3 illustrate how the economy is raised by increasing the temperature. It is seen that the increase in economy is gradually lessened after the temperature reaches about 300 degrees. By continuing the curve it would indicate that the point would soon be reached where an increase in the temperature would not cause any further increase in economy, this point being reached at about 450 degrees.

The results obtained in these experiments afford a very interesting comparison of the effects produced by different degrees of reheating, as well as by the use of different working pressures. Of the three different series of runs taken, the one employing the lowest pressure (56 pounds) seemed to give the most efficient results.

It was not considered advisable with the engine to raise the temperature of the entering air much above 400 degrees, on account of the bad effect it would have on the packing in the valve rod and piston rod glands, and also on the lubricant; however, a much higher temperature could have been attained with the reheater used.

Although the economy derived from the application of heat to the air may result from the increased volume, the experimenters were led to believe that the high results obtained are due partly to other changes of condition in the working of the engine, resulting from the higher temperatures. By reheating the air the engine is relieved from the difficulties due to freezing of the moisture in the exhaust passages and the choking up of the valve. It was noticed that as the temperature of the air was raised while the pressure remained constant, the speed of the engine was increased, the cut-off was made shorter, and in general the operation of the engine was rendered much smoother.

Mechanical efficiency, per cent	69.2	71	75.9	75.6	79.9	79.3
Free air per B. H. P. per hr.	3,030	2,085	1,901	1,790	1,658	1,688
Air saved, per cent	...	31.2	37.3	40.9	45.3	44.6

By referring to the curves in Figure 1 it is seen that the decrease in consumption of air is in almost direct proportion to the increase in temperature, until the higher temperatures are reached, when the decrease becomes more gradual, and finally ceases when the temperature is raised above the limit of practicability. In Series I., which employed a pressure of about 56 pounds, it is seen that a saving of 44.6 per cent. of the air used cold was effected by reheating it from the temperature of 59 degrees to 401 degrees. With Series II. and III., in which higher pressures were used, the gain was not quite as much.

Referring to the results obtained in Series I., the maximum gain in air saved with the highest temperature is 44 per cent. of the amount of cold air required to produce the same amount of power, which indicates that the power derived from the same weight of air would be increased about 78 per cent. by reheating it from 60 degrees to 400 degrees. In other words, a compressor which is able to supply 100 horse-power at the motor with cold air could be made to supply 178 horse-power by the use of reheaters. As the increase in volume obtained by raising the temperature of the air for this amount is only 65.3 per cent., it will be observed that the increased saving must be due partly to the more favorable conditions that the heated air provides for the engine to operate under.

The percentages of gain given in the results refer to the brake-horse-power, and the increased mechanical efficiency caused by the use of heated air must have a considerable effect upon the results. The increase in mechanical efficiency is shown by the curves in Figure 2.

Three important points are secured by the use of a reheater, viz.: (1) absence of freezing, (2) reduced cost of plant throughout, and (3) great increase in permanent economy.

Sewage Purification Experiments at York, England.

The subject of sewage disposal was very carefully investigated at York, England, during the last few years under the direction of the city engineer, Mr. Alfred Creer, M. Inst. C. E., whose elaborate report on the subject will be reviewed in the following notes. In consequence of complaints from the West Riding Rivers Board as to the unsatisfactory character of the effluent turned into the Ouse River from the chemical precipitation works at Naburn, investigations were begun to determine the feasibility of a further purification by passing the effluent over land. Trial holes were opened in various parts of the 18 acres available, but it soon became evident that the land was most unsuitable for such a purpose and that if it was used for sewage treatment the result would probably lead to a more serious nuisance than that arising from the discharge of the effluent from the precipitation works directly into the river.

After about a year's negotiations it was decided in the fall of 1898 to lay out experimental works with the view of "obtaining reliable data as to the effects of the various methods of treatment." The original plan included experiments with filtration on prepared land, with artificial filters and with a closed septic tank; but further experiments were suggested from time to time and were carried into effect. The following is a list of the experiments made: (1) Treatment of sewage by covered septic tank and single contact; (2) treatment by double contact bacteria beds; (3) treatment by a "ladder" filter; (4) treatment by open septic tank and continuous filtration; (5) treatment by open septic tank and double contact beds; (6) treatment of filtrate from experiment No. 1 through prepared land; (7) treatment of sewage by open septic tank and intermittent gravel filter.

For a proper understanding of the conditions, it should be stated that the sewage of the city gravitates to the pumping station at Fulford, where it passes through coarse screens and is then pumped to the disposal works at Naburn. For some years after the opening of the works it was found necessary to remove by hand large quantities of sand that accumulated in the reservoirs or pump culverts directly under the engine house. Since November, 1899, however, no such removal has been necessary, everything passing the coarse screens being carried to the disposal works. The sewage when delivered at Naburn was therefore very much worse to deal with during the experiments than it was when the sand was to a large extent deposited at Fulford.

For the purpose of these experiments a 15-inch pipe was laid from the sewage channel along the side of the precipitation tanks to a gauge chamber where sluice valves and gauges were fixed to control and measure the quantity treated. Under normal conditions the sewage occupies about five hours in flowing from the center of the city to the disposal works. To insure fair average samples of the sewage being obtained for analysis, portions were taken every half hour for ten or twelve hours, generally from 8 A. M. to 8 P. M. These were put into a bucket and well mixed before being sent to the analyst. Samples of the effluent from the continuous filter were obtained in a similar way, representing the flow over a lengthened period.

The provisional standard of purification fixed by the West Riding Rivers Board, with which the results obtained were compared, is one grain per imperial gallon of oxygen absorbed, and one-tenth of a grain per imperial gallon of albuminoid ammonia, which are equivalent in parts per 100,000 to 1.429 and 0.143 respectively.

Experiment No. 1. Covered Septic Tank and Single Contact Bed.—The tank was of concrete, of 48,000 U. S. gallons capacity, and as nearly airtight as possible. The sewage entered by three inlets 3 feet below the surface, and was withdrawn at the same level. The four contact beds were each 40x20x3 feet deep, with floors of concrete and sides and division walls of sod backed with clay puddle. Later, however, owing to the ravages of moles, the sod walls were removed and the sides lined with brickwork, the filters being reduced to half their original area. The material for filling the beds was clinker, cinder and coke. It was graded from ⅜ to 1¼ inches and put in in three layers, the larger material being at the bottom. It is stated that in all the experiments very little of the filtering material was of a quality best suited for the purpose; much of it was insufficiently burned, with the result that it soon became disintegrated and was partly washed out with the filtrate.

In this first experiment the gauge was set so as to allow a flow into the tank at a rate of from 15,600 to 48,000 gallons per day, giving a stay in the tank of from one to three days. The beds were worked in cycles varying from 8 to 12 hours. For the 8-hour cycle, two hours were occupied in filling, two in standing full and the remainder in emptying and standing empty. For the 12-hour cycle the time of filling was extended to three hours. When the working arrangement permitted, each bed was given a week's rest in rotation, that is, once in four weeks. The best results were obtained with a cycle arranged as follows: Filling, 1½ hours; standing full, 2 hours; emptying and and standing empty, 4½ hours.

At first one of the contact beds was used for a few weeks with the effluent from the chemical precipitation tanks. This had already been purified to the extent of about 56 per cent. before passing into the contact bed. The total purification obtained was from 85 to 90 per cent. However, as the object of the experiments was to determine the advantage of bacterial methods over chemical treatment, this arrangement was discontinued.

For the first period of working, from April 24, 1899, when the experiment was begun, till October 28, 1900, the area of the contact bed was 355½ square yards, and the average rate at which the sewage was passed through, including rests, was 249,100 U. S. gallons per acre per day. For the second period, from December 10, 1900, to August 31, 1901, the area of beds was 177¾ square yards, and the rate was 705,900 gallons per acre per day. The total quantity of sewage passed through the beds up to August 31, 1901, was about 17½ million U. S. gallons, and it is stated that the maximum depth of deposit at that time was 14 inches.

In the analyses of the effluent, slight traces of calcium nitrate were observed on only two occasions. The free ammonia was reduced from an average of 4.16 parts per 100,000 to 2.43. The purification in parts per 100,000 effected is shown by the following table, seven values being given in the report for each period:

	Alb. ammonia. Sewage.	Alb. ammonia. Effluent.	Oxygen absorbed. Sewage.	Oxygen absorbed. Effluent.
First Period.				
Max.	0.70	0.37	4.78	1.57
Min.	0.30	0.16	2.31	0.67
Avge.	0.54	0.27	3.52	1.15
Second Period.				
Max.	1.35	0.30	7.96	2.87
Min.	0.36	0.04	1.74	1.04
Avge.	0.72	0.18	4.29	1.54

The results of this experiment were distinctly disappointing in view of the success of the system in other places; and Mr. Creer was unable to account for its failure. He states that everything possible was done with the means at his disposal to make the experiment a success.

Experiment No. 2. Double Contact Beds.—These beds were 90x30 feet in size and 2 feet 9 inches deep, and were placed at different levels so that the entire contents of No. 1 could be discharged directly onto No. 2. The floors were of concrete and the walls of sod backed with clay puddle. The filling material was the same as that used in the previous experiment, but in No. 1 it was larger, being 1¼ to 3 inches in size, the coarser material on top. In bed No. 2 the size of the material was ⅜ to ¾ inch. These beds were filled once in eight hours except on Saturday, when they were filled only once, and Sunday, when they remained empty all day.

This experiment was a far more severe test than the one preceding it. The raw sewage was run directly onto contact bed No. 1, with no attempt at preliminary sedimentation. In order to fill the bed in the shortest possible time (about one hour), the flow through the 15-inch pipe leading from the sewage channel was for one hour in every eight increased from 34 to about 240 gallons per minute. As a consequence, every time the sluice to this bed was opened, large quantities of sludge that had been deposited in the pipe during the slow flow were washed out onto the surface of the bed. Under these circumstances it is not surprising to find that the liquid capacity of bed No. 1 was rapidly reduced, though a marked restoration resulted from periods of rest.

The total capacity of the basin was 55,200 U. S. gallons. On June 13, 1899, after the clinker had been put in and the bed filled with sewage a few times, the liquid capacity was 22,260 gallons, or about 43 per cent. of the gross contents. On September 11, after about 90 days' use, the capacity was reduced to 11,160 gallons, about half what it was before. As a result of 14 days' rest the capacity had increased to 16,380 gallons and after 42 days' use had become reduced again to 11,520 gallons. Subsequent tests showed the absolute necessity of frequent periods of rest. On several occasions the surface of the bed had to be forked up, and twice dried sludge to the extent of a cartload had to be removed from the surface. In no case did the liquid capacity of the bed become reduced to below 10,800 gallons, owing probably to the bed being allowed to rest every Saturday afternoon and Sunday. It was twice necessary to put additional clinker on bed No. 1, owing to the settlement and disintegration of the material. No appreciable reduction in the liquid capacity of bed No. 2 was observed during the experiment.

During the time these beds were in use, from June 13, 1899, to October, 1900, there were passed through them 11,138,900 U. S. gallons of sewage, the rate, including rests, being about 183,500 gallons per acre per day. A summary of the nine analyses given in the report is as follows, values being given in parts per 100,000:

	Alb. ammonia. Sewage.	Alb. ammonia. Effluent.	Oxygen absorbed. Sewage.	Oxygen absorbed. Effluent.
Max.	0.70	0.21	4.78	0.96
Min.	0.30	0.10	2.31	0.33
Avge.	0.52	0.145	3.34	0.64

It will be seen that in both cases the averages were practically within the provisional standard of the West Riding Rivers Board, although in the albuminoid ammonia test about 50 per cent. of the results were worse than the standard. On one occasion only was calcium nitrate present in the effluent in measurable quantity, although on five other occasions there were traces. The average of the free ammonia in the sewage was 4.70 parts per 100,000 and in the effluent, 1.21.

The results obtained from this experiment were on the whole very satisfactory, the main objections to this arrangement being the limited quantity of sewage that can be treated per acre of filter, and the loss in capacity of the beds.

Experiment No. 3. Ladder Filter.—This filter was composed of ten chambers, each 4 feet by 3 feet 5 inches by 2 feet deep, filled with similar clinker to that used in the first experiment. Each successive chamber was placed 6 inches below the previous one, and was separated from it by a 2-inch flag division. Under each alternate division a space about 2 inches in depth was left. The raw sewage flowed onto the first chamber, passed through the 2 feet of filtering material, under the division into No. 2, up through No. 2, over the next division into No. 3, down through No. 3, and so on, passing altogether through about 20 feet of filtering material, the liquid being aerated by coming in contact with the atmosphere in passing over the top of each alternate division. Facilities were provided for emptying each pair of chambers for the purpose of aerating.

This filter was brought into use on June 8, 1899, and was continued at the rate of 3,310 U. S. gallons per day until July 13. On July 4, the purification was 82 per cent., three days later it was 71 per cent., and on the 13th, it had deteriorated so much that the filter was stopped and divided into two separate sections of five chambers each.

A new start was made on July 17 at the rate 2,160 gallons per day to each section, but notwithstanding additional periods of rest, the purifying power of the filter deteriorated steadily, and further experiments with it were abandoned on September 15, 1900.

Experiment No. 4. Open Septic Tank and Continuous Filter.—In February, 1900, it was decided to convert one of the chemical precipitation tanks into an open septic tank, and to construct a circular filter. The supply pipes for the tank, perforated with 2-inch holes, were supported on old iron rails along one side of the tank about three feet from the bottom, and along the other side similar pipes were provided for the effluent, which then flowed into an open channel and finally reached the filter through 8-inch cast-iron pipes which were carried down under the floor of the filter and then up again above the surface of the clinker. The form of distributer used spread the tank effluent over the whole area of the filter in the form of fine jets.

The filter, for which the name York is proposed, is circular, 67½ feet in diameter. The floor is of Portland cement concrete with radial grooves 1½ inches wide and deep, beginning 3 feet from the center and terminating at the outer edge, where they are about 6 inches apart. From the center to the circumference the floor has a fall of about 6 inches. Around the floor, and forming a part of the same construction, is a shallow channel 2½ feet wide, to receive the filtrate as it leaves the filter.

On the concrete floor about 6 inches from the channel, a 9-inch brick wall was built up in pigeon-hole work, 8 feet 9 inches in height. The space inside this wall was filled with clinker to a depth of 6½ feet. Some of the clinker was of fairly good quality, but a large proportion of it was insufficiently burnt, and even after 13 months' use continued to flow out with the effluent in the form of a very fine ash. As the clinker was put in and levelled, perforated unglazed pipes 4 and 6 inches in diameter were laid radially at intervals of 2 feet vertically, making three series of them. In all 24 of these air ducts were laid.

The tank was filled with sewage on June 26, 1900, and allowed to stand full until July 5, when it was assumed to be sufficiently prepared to begin treatment. For the first seven weeks there was only 5 feet of filtering material in the filter. On July 24, 1900, while passing 1,219,000 U. S. gallons per acre per day, analysis of the effluent showed the oxygen absorbed to be 0.46 and the albuminoid ammonia 0.046 parts per 100,000. From July 5, 1900, to August 31, 1901, the tank and filter were not stopped more than 31 days in all, the longest rest being six days. The quantity of sewage dealt with varied from 1,219,000 to 4,850,000 U. S. gallons per acre per day, averaging 2,555,500 gallons, and the total quantity dealt with up to August 31, 1901, was about 82½ million gallons, and the total quantity of sludge in the tank on September 9, was 225 cubic yards.

The analysis of the effluent gave very uniform results during the whole period, well within the standard adopted, and seemingly regardless of the rate of filtration or the percentage of impurity present in the sewage. The following table giving values in parts per 100,000, is condensed from the tabulated results of forty tests:

	Sewage.	Effluent.
Oxygen absorbed:		
Max.	9.92	1.28
Min.	1.74	0.16
Avge.	4.32	0.67
Albuminoid ammonia:		
Max.	1.70	0.140
Min.	0.35	0.030
Avge.	0.73	0.071
Nitrogen as calcium nitrate, avge.	0.00	11.56
Free ammonia, avge.	3.94	0.26
Chlorine, avge.	12.81	10.42

For about ten months after starting the experiment no permanent scum formed on the surface of the septic tank. At the end of the period the scum averaged 2 inches thick, but it was evidently not a necessity to the proper working of the tank, but rather an incident to the liquefaction of the solids.

In regard to the condition of the filter, it is stated that the portion of the filtering material near the surface became coated with a gelatinous substance containing a large number of small thread-like worms, some red in color, while others had the same colorless appearance as the substance adhering to the cinder. In addition to the worms there were large numbers of small flies not only in the pigeon holes of the containing wall but throughout the whole filter where it had been examined. Occasionally large numbers of the worms were washed out, probably accounting for the many fish at the outlet of this tank.

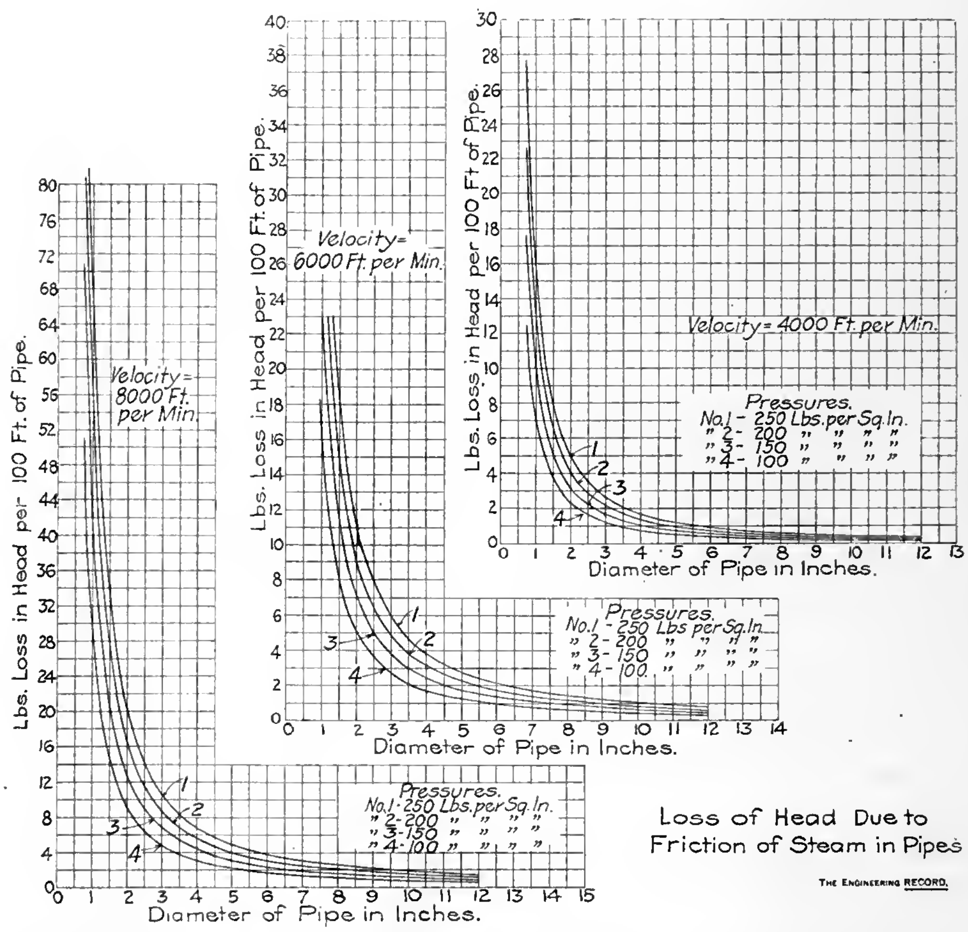
Experiment No. 5. Open Septic Tank and Double Contact Beds.—The same beds used in Experiment No. 2, after a rest of 39 days, were used for this also. During the rest bed No. 1 had been forked up and about 6 inches of the top replaced with clean material. Operations were begun with these beds on November 23, 1900, with three fillings per day of effluent from the open septic tank, and continued till July 1, 1901. Durin~ this period 5,868,000 U. S. gallons of tank effluent were passed through the beds, at a rate of about 215,000 gallons per acre per day. The poor results obtained from these contact beds, both in this experiment and when they were used with crude sewage, may perhaps be partly explained by the fact that on opening up bed No. 1 the material was found to have solidified to a considerable extent, and to be like a mixture of ordinary soil with ashes and fibrous material.

The effluent gave better average results by the albuminoid ammonia test than when the crude sewage was used on the beds, although the results were not quite so good by the oxygen absorbed test. The following is a summary of the sixteen analyses, in parts per 100,000:

	Sewage.	Effluent.
Oxygen absorbed:		
Max.	7.95	1.68
Min.	1.75	0.42
Avge.	4.32	0.92
Albuminoid ammonia:		
Max.	1.50	0.28
Min.	0.36	0.03
Avge.	0.79	0.10
Nitrogen as calcium nitrate, avge.	0.00	2.81
Free ammonia, avge.	3.07	0.57

Experiment No. 6. Effluent from Experiment 1 on Prepared Land.—A quarter of an acre of land was divided into two plots, trenched 2½ feet deep and underdrained. After using the plots for about two months the surface began to cake over, and it is stated that the effluent from the contact beds would lie on the surface for weeks, showing the unsuitability of the land for filtration purposes.

Experiment No 7. Open Septic Tank and Intermittent Gravel Filter.—The tank was 7 feet 10 inches square and 1 foot 9 inches deep, holding about 787 gallons, and was provided with an Adams' automatic syphon. The filter was something over 19x11 feet and 3 feet deep, with walls of pigeon-hole brickwork. It was filled with clean gravel as follows: 9 inches of 1½-inch at the bottom, then 9 inches of ¾-inch, then 9 inches of ½-inch, 4½ inches of ⅜-inch and 4½ inches of coarse sand.



Loss of Head Due to Friction of Steam in Pipes

When the liquid in the syphon chamber reached a certain depth the contents of the tank were discharged over the whole surface of the filter by means of a perforated trough, covering the filter to a depth of about 2 inches. Although various periods of discharge were tried, no satisfactory filtrate was obtained during the eight months the experiment was in operation.

In conclusion, Mr. Creer recommended to the consideration of the sewerage committee the results of experiment 4, the open septic tank and continuous filter.

The Friction of Steam in Pipes.

Among the theses presented by the class of 1902 of the Virginia Polytechnic Institute was one by Messrs. W. L. Chewning and W. P. Tams, Jr., on the friction of steam pipes. This contained a number of diagrams plotted from tables prepared particularly for the use of designers of power plants, and was sent to this journal by Prof. L. S. Randolph because of the useful data it contained. The introduction explains the general form of the equation for the flow of steam by comparing it with that for water. For the latter, assuming there is no friction, h, the loss of head, is equal to $v^2 \div 2g$ by the law of falling bodies. Friction exists, however, and varies directly as the length, l, and inversely as the diameter, d, so that the actual flow is more closely represented by $h = flv^2 \div 2gd$. Since 2g is a constant, this equation can be reduced to the well-known Weisbach expression

$$h = f' \, lv^2 \div d \ldots\ldots (1)$$

As water is almost incompressible, its density is not taken into account, but this must be done when the flow of steam is considered and the above formula modified accordingly. Experiments made under the direction of the Italian government many years ago show that the usual formula for the flow of compressible fluids through pipes could be used for steam. This formula is $Q = c \sqrt{(pd^5 \div wl)}$, where Q is the volume in cubic feet per minute, p is the difference in pressure in pounds per square inch causing the motion, d is the diameter in inches of the pipe, w is the density of the fluid in pounds per cubic foot, and l is the length in feet of the pipe. If W is the total weight of the fluid discharged per minute, $Q = W \div w$, and the equation can be written in the following form, $p = W^2 wl \div c^2 w^2 d^5$. But $W = kwvd^2$, where k is a constant, hence

$$p = k'wlv^2 \div d \ldots\ldots (2)$$

If formulas (1) and (2) are compared, it will be seen that the only difference in form is the introduction in the latter of the density. According to the Italian experiments, the value of c in $Q = c \sqrt{(pd^5 \div wl)}$ is 58, and this value might be used in determining k'.

A modification of this formula was introduced by Mr. G. H. Babcock and used by him in the computation of his well-known tables issued by the Babcock & Wilcox Company. It is

$$W = 87 \sqrt{(w \, p \, d^5 \div l \, [1 + (3.6 \div d)])} \ldots (3)$$

Comparing this formula and that of the Italian authorities, it will be seen to allow for a variation of the constant for different sizes of pipes. Thus, for a 1-inch pipe, the constant would be 40.5, for a 3-inch pipe 58.6 and for a 10-inch pipe 74.8. This formula was employed in computing the tables plotted in the accompanying diagrams. For changes in the initial pressure multiply the values in the diagrams by the ratio of the densities at the new and old pressures. The loss caused by a globe valve is stated to be about equal to that in a pipe of a length equal to $114d \div (1 + [3.6 \div d])$. The loss caused by elbows is two-thirds that due to globe valves.

Testing of Combined Steam-Engine and Dynamo Sets.

Extracts from a paper presented to the Institution of Civil Engineers by Edwin Hartree Rayner.

The exacting requirements of engineers and others, in specifications relating to the economy of generating-plant, have caused makers of engines used for the generation of electricity to instal apparatus for the rapid testing of steam-dynamo sets. This comprises special steam-raising plant, arrangements for controlling and dissipating the electrical output, and instruments for its measurement and for the measurement of the steam used by the engine. In the following paper the author proposes to outline the tests usually applied to such sets, and the methods used in the testing-shops of engine makers.

In England, where the manufacture of engines and dynamos is largely carried out by separate firms, the dynamo is usually sent to the engine maker with a coupling on the armature-shaft, by which it is fixed to the crank-shaft of the engine. The engine maker fits the two together and steams them according to the tests required. By this means, in a few hours, an insight is obtained into the economy of the set, such as it is almost impossible to acquire in a central station or private installation. The engine builders obtain, at the same time, data for future orders, and are able to effect improvements which would hardly be possible except by having most of their engines steamed under the eyes of men whose work it is to get engines to run satisfactorily, and who have had much experience of former engines. Satisfaction is given to customers by the fact that when finally erected the engines usually run satisfactorily at once. The performance of these tests is an important item in the cost of the engine to the builder. The methods now employed in all tests where reliable results are required in a reasonable time were instituted by the late Mr. Willans at Thames Ditton. High-speed-engine builders have now erected special buildings and laid down plant at considerable expense for the purpose; and engines up to about 1,200 horse power are now usually tested before leaving the works. Engines of over 1,500 horse power are more conveniently tested on site after erection, on account of the large boiler-power required and the cost of such a trial.

In the following paper the author proposes to deal chiefly with the work done in the testing department of Messrs. Willans & Robinson's works at Rugby. This department has been built entirely separate from the rest of the works. The engines (small sizes complete, ready for the steam and exhaust-piping; larger ones in parts) are brought on trolleys running on rails from the erecting-shop, the men from which erect the engine on the steaming-beds. The boiler-power required is considerable, as several engines are often running at once, if not on official trial, yet on preliminary runs to see that all is satisfactory. The rapid fluctuation in the demand for steam, due to the engines being continually started and stopped, necessitates the employment of a boiler readily controllable as to rate of steam-production; and, as it is usual to run all engines off a common steam-pipe, the boilers must easily maintain the highest pressure required by modern triple-expansion engines, viz., about 200 pounds per square inch. These requirements are best fulfilled by water-tube boilers, and at Rugby there are installed four Niclausse water-tube boilers rated at 250 horse power each, but which easily produce 400 horse power. They are also used to supply steam, day and night, to two engines driving the dynamos which supply power for the traveling cranes, forty in number, the pattern-shop machinery, circulating pumps for the condensers, and for lighting the whole of the works. These engines are three-throw engines of standard pattern with two-pole dynamos, rated 900 amperes at 120 volts. A power-house is now in course of construction, in which electricity will be generated for works' use; electrical power-transmission will soon be completely installed for all purposes, and larger generators will be used. The steam arrangements include three duplicate feed-pumps, a Green economizer of 192 tubes, with motor-driven scrapers, and two motor-driven circulating-pumps for the surface-condensers. The water is purified in two settling-tanks, in which it is softened by the Archbutt-Deeley process. A railway siding passes the boiler-house door, and the covered bunkers are capable of storing large quantities of coal.

The testing-shop consists of four bays, in which the dynamos and condensers are placed. Each is served by two electrically-driven traveling cranes. In the front, away from the boiler wall, there is a pit, 3 feet in depth and 6 feet in width, in which the field-magnets of large machines are fixed, and over which large fly-wheels are hung, as by this means the engine itself is kept down and is therefore more easily steadied. There is also in one bay a shorter parallel pit. The engine bed-plate is usually planed underneath and supported on girders about 1 foot high, which are bolted to cast-iron slots grouted into the cement floor. In small sets the magnets are fixed on the same bed-plate as the engine, and in larger sets they have to be packed up to the required height either from the floor-level or from the pit-bottom. The floor furthest away from the boilers is raised, and on it the engines are placed after the trial, and are taken down, examined, oiled, and, in the case of the smaller ones, re-erected.

All electrical readings are made in the weigh-bridge room, where the steam used by the engine is weighed after it comes out of the condenser, and where practically the whole trial is made. There is also an underground system of pipes by which the exhaust of an engine may be taken to the atmosphere. One person sitting before the weigh-bridge beam has before him a clock, on the one side a bell to signal to the driver or persons indicating the engine, on the other the shunt-resistance controlling the output of the machine, and in full view the scales reading by reflected light the output of the machine. By this means the consumption of steam by the engine is obtained in a few minutes with greater accuracy and satisfaction than if it were done by the older method of measuring the feed-water supplied to the boiler, which with all its losses and inaccuracies would require as many hours. It would be the work of several days to obtain satisfactory results by the latter method from an engine tested at full, three-quarter, half and quarter load, both condensing and non-condensing, such as can be done by the former method between breakfast and dinner hour.

Numerous pipes supply live steam to the engines by means of temporary copper and wrought-iron piping, and there is usually a separator for removing the water in the steam on the engine bed-plate, as well as separators permanently fixed to the steam mains. Loose flanges enable the connection of the temporary steam-piping to be easily made. The condensing water is taken from a main supply-pipe by means of flexible pipes, and is discharged through a special drain into one of the condensing ponds. The steam used by the engines is condensed in a surface-condenser, and gravitates into one of two tanks on weigh-bridges. In the case of condensing trials, it is pumped out of the condenser by the air-pump. The layer of oil on the top of the water prevents any undue evaporation from the surface of the warm water in the weigh-tank. The main current from the dynamo is carried by temporary cables to terminals on wooden boards fixed on the pillars supporting the roof. The mains run to the screw-plug testing switchboard, from which some twenty circuits lead to resistances in the resistance-room, where the energy is dissipated by passing the current through iron-wire netting or through water-tanks. To smaller terminals are connected two wires from the main terminals of the machine, by which the effective voltage is measured, and two others are similarly provided for the exciting circuit, whether the machine be self or separately excited.

The field-coil circuit is taken to the instrument room, where temporary connections are made to shunt-resistances and switches, and an ammeter is placed in the circuit. By means of the shunt-resistance the load on the machine is adjusted. In ordinary working the field-coils of a shunt-wound machine gradually increase in resistance after running for some time, as they become heated by the current. The extra resistance in the circuit has therefore to be reduced as the machine becomes warm, if the voltage is to be kept constant. The testing switchboard on the gallery is divided into an upper and a lower panel, one for each pole of the machine. It consists of a number of horizontal bars to which the machine terminals are connected; and at the back of the switchboard are a number of vertical bars connected to resistances in the resistance-room, through a switch by the making or breaking of which the load, or part of it, is put on or taken off the machine being tested. By screwing plugs into holes in the back bars, any machine may be put on to any of the resistances in the resistance-room. In the latter the frames are arranged, chiefly by means of copper connections in mercury cups, to suit the voltage of the machine. The current, per switch, is usually about 100 amperes with 500-volt machines, and 200 amperes or more at lower voltages. By means of copper bars from the adjacent lighting switchboard the whole load of one of the lighting engines may be taken up on the frames for experimental purposes, or current may be taken for any special purpose, as may be required. Arrangements are provided by means of which the field of any machine may be at once excited, if required, from the ordinary lighting circuit or battery, or by any other machine which may happen to be running at the time on the testing-beds.

The most important point to be ascertained in the economy of a steam-dynamo is the amount of steam consumed by the engine for a given output of energy by the dynamo, or the number of pounds of steam required by the engine per electrical horse power-hour, or per kilowatt-hour, developed by the dynamo. As an engine is more economically worked if fully loaded, it is of great importance to determine how the consumption per electrical horse power-hour, or per kilowatt-hour, increases as the engine is more lightly loaded. For this purpose tests are often made at three-quarter, half, and quarter load, as well as at full load. The water running out of the condenser or air-pump falls into one of the weigh-tanks in a pit below the level of the floor. In measuring the steam-consumption the weight on the beam is moved along till it overbalances the water. As the tank fills, the beam rises and causes an electric bell to ring, and the observer notes the hour, minute and second on the clock. He sets the weight forward a certain amount, varying between 10 pounds and 300 pounds according to the size of the engine and its load, so that the bell will ring again in about a minute. At each observation note is made of the electrical output of the machine in volts and amperes; and, if the water is found to be coming out steadily from the engine, 20 minutes is usually a sufficient length of time to ascertain the steam consumption of the engine for all practical purposes.

Two of the most important quantities to be observed are the current produced by the dynamo, and the voltage at which it is generated. In testing-works, where currents of hundreds of amperes and also currents of small fractions of an ampere have to be measured daily, it is evident that without very carefully designed instruments a large number of these might be necessary, since measurements accurate to one-third per cent., and often even more accurate, are required.

At Rugby the system used for the measurement of continuous currents was designed by Capt. H. R. Sankey, R. E., M. Inst. C. E., and the late Mr. F. V. Andersen, and the adaptability of one of the instruments to measurements widely different in magnitude is remarkable. In measuring current the same instrument is used to measure 2,000 amperes and 0.000002 ampere, accurate to within one-third per cent., and a similar instrument is used to measure voltage between 1,000 volts and 0.001 volt. The system used is a direct deflection method. The current from the machine passes in its circuit through a standard low resistance of a few ten-thousandths of an ohm. The difference of potential between the ends of this resistance, if the resistance be constant or practically so at all temperatures reached in practice, is proportional to the current flowing. Two wires from the ends of this resistance are connected to a galvanometer in the instrument room, and in the circuit is a resistance so calculated that the galvanometer, which reads by light reflected from a small electric lamp, shows amperes direct on the scale, which is 1 foot 8 inches in length, and is divided into 200 parts, each of 0.1 inch. If the current is over 200 amperes the resistance is so arranged that the scale-reading is one-half or other fraction of the total current. By using main resistances of different capacity and magnitude, currents of largely different value can be easily measured, reading direct in amperes or multiples or submultiples of an ampere. The current taken by the galvanometer is an inappreciable fraction of the whole—about one-millionth. The galvanometers used are of the d'Arsonval type, in which the current passing round a coil suspended in a magnetic field produced by a permanent horse-shoe magnet tends to deflect the coil. The restoring couple is supplied by the fine strip of metal which supports the coil and also leads the current to it, a similar strip below acting as the other conductor. This type is the only one available for the work required, as the large and variable currents dealt with would, by the magnetic field they produce, render useless any other type of galvanometer. The measurement of voltage in the case of continuous currents is done in a manner similar to that used for the measurement of the current.

One of the most important quantities to be determined is the indicator-horse power of the engine. For this purpose an indicator is fixed on to each cylinder, and communication with the receiver above is also effected, by means of a three-way cock. The motion for the indicator-drum is derived either from an eccentric on the shaft or from an inclined plane on the cross-head, by a plunger acting through the crank-chamber door. The indicating is done on an electric-bell signal being given from the weigh-bridge room, where bell-pushes are placed near the scales on which the amperes and volts are read. Usually three complete sets from each indicator are taken, the electrical readings, speed, steam-pressure, and vacuum being noted at the same time. When an engine is indicated at different loads, it is usual to plot, on squared paper, the indicator-horse power against the output of the dynamo. The results usually fall on a straight line, from which the efficiency is at once obtained. The steam-consumption of the engine is also plotted in a similar manner, the steam used, in pounds per hour, against the dynamo output. This gives at once consumption per electrical horse power-hour or per kilowatt-hour, and, from the efficiency curve, the consumption per indicator-horse power-hour.

It has been found desirable to test all pressure-gauges and indicator-springs used. The apparatus employed for this purpose consists of a vertical cylinder of copper partly filled with water, which is acted on by steam pressure from the boilers, and is in connection with a small ram of 0.1 square inch in cross-section. This ram is loaded with 1 pound weights, every 1 pound representing a pressure of 10 pounds per square inch when the ram is just balanced. The balance is obtained by allowing steam to escape by a needle-valve. By adjusting this valve and the inlet-valve the pressure may be kept nearly constant at any desired amount, and the reading on the gauge is noted when the ram is just balanced. There is an attachment to which an indicator is fixed for testing indicator springs, which are thus tested at their working temperature.

A Froude hydraulic brake, made by Messrs. Mather & Platt, of Manchester, is used for measuring brake-horse power. It absorbs the power of the engine by churning water which passes through it. The power is measured by hanging the required number of 80-pound weights on the end of a lever, the smaller adjustments being made by a jockey-weight. By adjusting the cocks controlling the inlet and outlet of the water, the beam is made to balance horizontally. From the weight on the lever, the distance of the weight from the center of the shaft, and the speed of the engine, the brake-horse power is obtained. The brake is capable of absorbing about 700 horse power at 250 revolutions per minute, and will keep the beam horizontal automatically if required.

The Expansion of Concrete has been investigated by Mr. C. A. Lyford in the physical laboratory of the Worcester Polytechnic Institute. Earlier experiments already mentioned in this journal gave the expansion as 0.0000115 per degree Centigrade. Later tests of two bars have given 0.0000102 and 0.0000115 as the mean values between 20 and 50 degrees Centigrade. These results are slightly higher than those obtained by Professor Pence and described in this journal on February 22.

A Large Sewer Tunnel Contract in Brooklyn, N. Y., for which proposals will soon be asked, is now occupying the attention of contractors. The sewer, which will be for both surface and house drainage, is to be 13 feet in diameter, 6,200 feet long, and will furnish long-desired sewerage facilities for the Dyker Heights section. When ultimately extended eastward it will reach Bensonhurst. The outlet will be at 92d Street and New York Bay. The estimated cost of the work is stated by Mr. H. R. Asserson, chief engineer of the Bureau of Sewers, to be $665,000.

The Blair Building, New York.

The 76½x80-foot Blair Building at Broad Street and Exchange Placé, New York, is a steel-cage office building twenty stories high above the curb. It has 35 steel columns on concrete piers sunk by the pneumatic caisson process to rock at about 45 feet below the curb. The cellar floor will be from 27 to 31 feet below the curb and about 14½ feet below the ground-water level at the deepest place. Two of the interior caissons are rectangular and support two columns each, the remaining eight are from 8 to 9 feet in diameter and each supports one column on the center line. The caissons for the wall columns are from 6 to 7 feet wide, from 13 to 40 feet long, and are arranged to form a continuous enclosure around all sides but one of the lot.

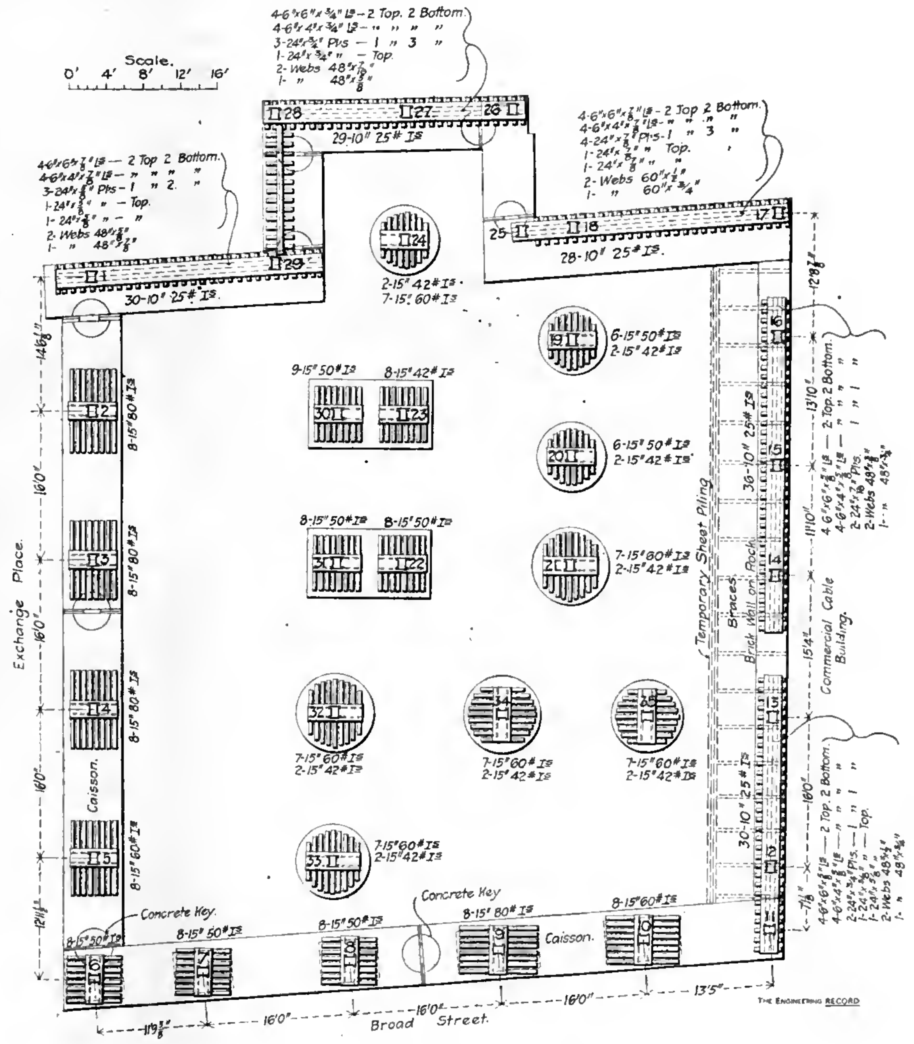
The cellar floor in the old building was from 7 to 9 feet below the curb, and through it four test holes near the corners of the lot were sunk from 34½ to 36 feet deep to hard bottom before the old building was removed. The lot was excavated to about 12 feet below the curb or 2½ feet above the ground-water line, and caisson sinking was commenced June 20. All caissons had vertical wooden staves 4 inches thick secured to interior horizontal angle-iron frames by bolts with countersunk heads which left a smooth exterior surface. The bottoms of the caissons had steel-plate cutting edges and the working chambers of the cylindrical ones had removable domed steel roofs and air shafts similar to those described in previous articles on foundations in this journal. The lower sections, which were the caissons proper and included little more than the working chambers, were uniformly 9 feet high. Their walls were carried 28 feet higher by two sections which were really simple cofferdams connected to them and to each other by vertical bolts through the top and bottom inside horizontal flange angles.

All of the interior caissons and cofferdams were sunk through guide frames of horizontal timber rectangles with a clearance of 2 or 3 inches from the caisson on each side, and fillers packed in the center of each side in contact with the caisson, which had the corresponding stave well greased at its bearing. The frames were diagonally braced to the bottom of the general excavation and served to preserve the verticality of the caissons. The cylindrical caissons were loaded with pig iron filled in between the air shafts and the cofferdams and handled by small hoisting engines which operated light tackles suspended from brackets above the tops of the cofferdams. A 6x6-inch vertical timber was bolted to the side of the cofferdam, and at the top, 10 feet above the upper edge, there was attached to it a simple swinging bracket about 3 feet long made of a pair of small channel bars back to back with a sheave between them for the hoist rope at their outer end, which was guyed to the top of the vertical piece. The spoil was hoisted out of the caissons in cylindrical steel buckets which were inverted by snubbing a line attached to their bottoms while they were being lowered, and thus dumped their contents on platforms whence it was shoveled into wagons and carted off before a large quantity was allowed to accumulate. Concrete was lowered into the caissons in cylindrical steel buckets with automatic flap doors in the bottom.

At the corners the wall caissons overlapped and were nearly at right angles to each other with the end of one abutting against the side of the other with very small clearance. Adjacent to the line of contact in each caisson a semi-cylindrical well was left open when the working chamber and cofferdam were filled with concrete. The straight side of the well corresponded to the vertical sheathing boards and the curved side was enclosed by expanded metal centering on braced wooden scarf boards. After both caissons were sunk the sheathing planks at the edges of the wells in both walls were bolted together, the center ones removed and the edges of the opening calked, thus establishing communication between the working chambers and cofferdams of both caissons and making the two wells into a single one of approximately circular cross section with two vertical radial diaphragms composed of the sheathing planks extending half way from the circumference to the center on opposite sides. The well was grouted and concreted and the two caissons were thus keyed strongly together and a substantially watertight joint was made between the caissons. Similar connections were made between the abutting ends of caissons in the same line in the middles of the walls. The caisson and cofferdam sections were delivered whole on wagons drawn by several teams.

The very long cofferdams were braced by interior transverse angles 5 or 6 feet apart, which were bolted to belt courses of flange angles about 4 feet apart vertically ou the sides of the cofferdams. The horizontal panels between them were braced by adjustable diagonal rods at the ends and in intermediate panels, which were removed as the cofferdam was concreted. Special care was taken to secure accuracy in the positions and dimensions of these foundations and the plans were made to 1/32 inch and lines and levels were frequently checked instrumentally by the engineers. The ends of the caissons were sunk with very slight clearance and the deviations from the perpendicular in sinking were slight. The general design and principal details of the caissons and methods of sinking them corresponded closely to those described for the New York Stock Exchange in The Engineering Record of September 28, 1901.

The building has street fronts on two sides, and as the wall caissons are well within the curb line no special precautions were necessary to prevent undermining the street. On one side, the lot is bounded by the continuous line of foundation caissons for the Commercial Cable Building, which are carried down to solid rock as described in The Engineering Record of April 17 and May 8, 1897, and on the remaining side the foundations of the adjacent building were underpinned before excavation was commenced for this building, by jetting down under them to solid rock, five 10-inch pipes which were filled with concrete. The same wall was braced with inclined timber shores which were seated on transverse timber sills across the tops of the cofferdams of the wall caissons.



Plan of Foundations, Blair Building.

After the wall caissons were all sunk they excluded the ground water and the interior excavation was made to the required depth with comparatively little pumping. The sheathing of the insides of the cofferdams was removed as the excavation progressed and the grillage beams were bedded on top of the concrete piers.

On the east side of the lot the wall columns are supported on a foundation wall which is carried down to bed rock about 50 feet below the curb and is built up solid against the caissons of the Commercial Cable Building. The pit for these footings might have been excavated in the open without special methods after the lot was enclosed by the wall caissons, but to expedite its construction it was commenced before the general excavation was made inside the caissons, and a row of 9-inch Wakefield sheet piles was driven across the lot between the wall caissons about 8 feet clear of the Commercial Cable Building caissons. This formed a cofferdam to exclude ground water and resist earth pressure and in it excavation was carried down to bed rock, the sheet piles being timbered and braced to the caissons as the earth was removed. The bottom of the trench was filled with concrete 4 feet thick and on it a brick wall 40 inches thick at the base was built and capped with short transverse grillage beams under the wall columns.

Different parts of the lot were successively covered by a heavy timber deck at street level, which was shored up from the bottom of the excavation and served for a working and storage platform and was shifted from place to place as the caissons were sunk. On it was placed a stiff-leg derrick with two 50-foot booms and two 30-foot vertical masts braced together about 15 feet apart. The masts are swung by bull wheels and the derricks were operated by two hoisting engines. A trestle bent about 40 feet long and 12 feet high, with seven vertical posts scabbed to a cap and to a bottom sill, was made of 12x12-inch timber, X-braced, and set up on the Broad Street building line. A similar parallel trestle was set 25 feet away, in the street beyond the curb line and transverse beams about 30 feet long were laid across the caps and cantilevered 5 feet beyond the street bent. They were kneebraced to the vertical posts and covered with thick floor planks which formed a roof protecting the sidewalk and forming a shelter over the edge of the street under which offices and small shops were located.

At the corners of the platform nearest the building, two vertical derrick masts were set and braced together in the plane of the trestle bent and farther secured by stiff legs anchored to the opposite side of the platform. Each mast had a long boom, swung by an independent hoisting engine, and these booms, with those previously described, commanded the whole area of the lot and handled all the caissons and cofferdam sections, which were delivered complete and weighed up to 16 tons or more each. The two air compressors, the pumps and the other machinery were located in the excavation, where there were also dressing rooms for the caisson men, who worked continuously in 8-hour shifts under pressure below 20 pounds at the maximum. Concrete was mixed by hand on platforms in the excavation and at the street level, and was handled in steel buckets lowered by derricks into the caissons, and by wheelbarrows from which it was dumped into the open cofferdams.

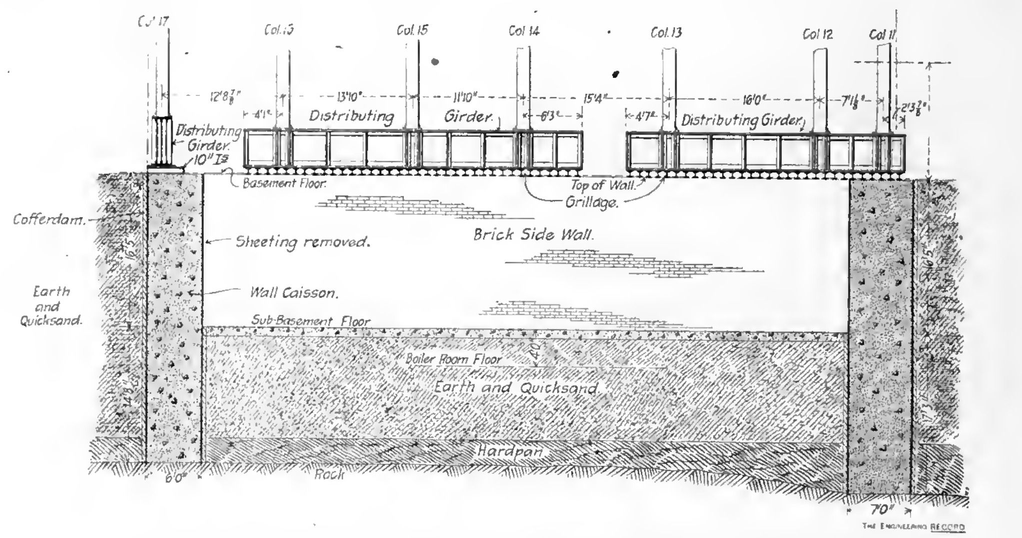
The last caisson was sealed July 22, thirty-two days after air pressure was put on the first one; the deepest caisson was excavated 52 feet below the curb and the most rapid sinking was about 2 feet an hour. The circular caissons were loaded with about 50 tons, and the largest rectangular caisson was loaded with 400 tons of pig iron. As the steel decks were removed from the working chambers of the circular caissons after they were concreted there was no concrete filled into their cofferdams until after the caissons were sunk to their final positions. The rectangular caissons had, on the contrary, flat steel roofs which were permanently left in position. On them the first two sections of the air shafts were permanently left in position. They were loaded with concrete 15 feet in depth to promote sinking, before the excavation was commenced. The foundation quantities included about 2,400 yards of caisson excavation, 4,000 yards of excavation around the caissons and 2,000 yards of concrete in the caissons and cofferdams. A total force of about 350 men was employed on the foundation work and was divided into two 12-hour shifts for the men outside and three 8-hour shifts for the men in the caissons. All the material above hard pan was excavated in the caissons rapidly and easily by shovels, but the hardpan required picking.

The tops of the concrete piers are levelled off 3¾ feet below the cellar floor for the interior columns and about 16½ feet higher, at the basement floor level, for the wall columns. The tops of the circular piers are nearly covered with grillages of six or seven 15-inch I-beams. The two rectangular interior piers and the wall piers on the two street sides have grillages consisting of sets of eight 15-inch I-beams from 6 to 8½ feet long, concentric with the columns. These piers are all symmetrically and concentrically loaded but the wall piers next to the adjacent buildings are eccentrically loaded on grillages of 10-inch transverse I-beams 3 feet long and about 1 foot apart, set close to the building line. In all cases about one-half of the surfaces of the wall piers are covered by the grillages.

The interior columns and the wall columns in the street fronts have extended bases made with wide gusset plates riveted across the cover plates at the lower ends and stiffened with flange angles to receive base plates which reach from side to side of the grillages and serve for distributing girders to transmit the column loads equally to all the grillage beams. On the wall piers next the adjacent buildings the columns have ordinary bases and are seated on distributing girders which reach from end to end of the piers. With one exception these girders have three webs and eight 6x6-inch flange angles. All of them have one or more 24-inch cover plates and the plates and angles are from ⅝-inch to ⅞-inch thick. One girder has webs 60 inches deep and one girder has a single 36-inch web. The longest girder receives columns 14, 15 and 16, and is 36 feet long and 48 inches deep; but is not as heavy as the girder 30 feet long, 5 feet deep and 2 feet wide which receives columns 17, 18 and 25 and weighs about 32,000 pounds. All grillages, girders and column bases receive two coats of asphalt paint and are entirely covered with fine rich concrete which is rammed between their webs and all interstices carefully grouted.

In the typical floors the columns are connected by pairs of I-beams in the planes of the exterior walls. The web of one beam is in the plane of the outer face of the columns and that of the other beam is a little inside the opposite face of the column so that the end of that beam abuts against the side of the column. The two beams are connected by cast-iron separators and are arranged so that the outer one carries wall load only and the inner one carries floor load only. Most of these beams are 12 inches deep, but in one case they are 18 and in another 20 inches deep. From each of the street wall columns except those on the corners a girder extends normal to the front of the building to a column in the next row of interior columns. These girders are all pairs of 18-inch 55-pound I-beams with riveted transverse diaphragms or separators and their webs engage the opposite faces of the columns. All other girders between columns are single I-beams from 9 to 20 inches deep, which are connected to them on the center lines of their faces.

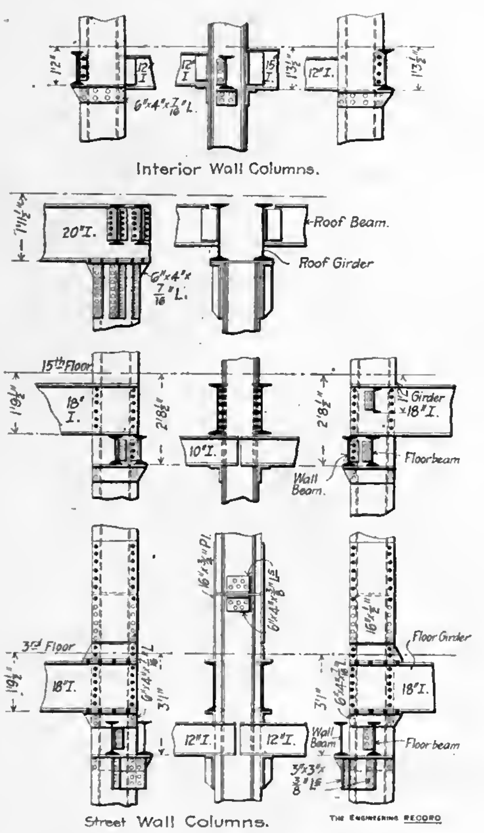
The floorbeams are of about 16 feet maximum span and from 4 to 5 feet apart on centers. They are single I-beams from 8 to 15 inches deep and are web-connected to the girders, with the top flanges flush with those of the girders and uniformly 3½ inches below the finished floor level except for the 8, 9 and 10-inch beams which have their bottom flanges 14 inches below the floor level. The beams have the usual horizontal tie rods from web to web and support flat hollow-tile side construction arches which are proportioned to carry a total load of about 200 pounds per square foot. The roof is similar to the floors except that it is slightly pitched and is proportioned for a total load of 150 pounds per square foot and is covered with hard burned thin flat tiles laid in cement instead of having a wood surface like the floors.



DISTRIBUTING GIRDERS ADJOINING COMMERCIAL CABLE BUILDING.

The columns all have a rectangular closed cross-section made with two channels and two cover plates, and are spliced about 18 inches above the tops of the girders by two cover plates and a horizontal diaphragm. The wall columns have bracket angles with reinforced horizontal flanges on which the wall beams are seated just beyond the face of the column. The parallel floorbeams are seated on the same angle but are additionally connected by a short vertical angle riveted to the beam web and to the face of the column. The floor girders have their flanges sheared on one side at the ends so that the webs lie flat against the faces of the sides of the columns and are riveted to their column cover plates. Their flanges are also riveted to top and bottom horizontal angles on the columns. In the upper stories these connections are slightly modified as shown in the elevations, by cutting the flanges of the wall beams to allow them to set closer to the columns and connecting them to the columns with short vertical angles like those of the floorbeams. The floor girders have their webs fillered out from the sides of the columns. The tops of the columns have cap plates bearing on the ends of vertical angles and supporting the lower flanges of the 20-inch I-beam roof girders. All beam and girder connections are made to the interior wall columns with single vertical web-connection angles and bottom bracket angles without reinforcement for their horizontal flanges. The beam and girder connections to the interior columns are made in the same manner, and all are field-riveted with pneumatic hammers.

The architects of this building are Messrs. Carrere & Hastings, and Mr. Owen Brainard, of that firm, is the engineer in charge. The structural steel work was designed by Mr. Henry W. Post, and is being supplied by the American Bridge Company who are fabricating it at their Pencoyd plant. The general contractor for the building is the Andrew J. Robinson Company. The caisson work and the general foundation work was executed by Mr. John F. O'Rourke, the work for him being in charge of Mr. T. B. Bryson. Mr. Brainard has expressed his very great satisfaction with the accuracy and expedition with which the foundation work was carried on, it having been completed before the expiration of the contract period. He considers it a first-class example of the efficiency and certainty of the building methods which have been made necessary and



Details of Columns.

developed by the extraordinary conditions prevailing in building operations in the downtown district in New York.

The Technolexicon or technical dictionary in German, English and French which the Society of German engineers has undertaken to prepare, is reported to be progressing satisfactorily. German contributors have been secured for words in 730 classes, English and American for 450 and French for 93. In addition 266 German societies, 23 English and American and 22 French have agreed to assist in one way or another.

Tar Macadam Roads in Nuneaton, Eng., were pronounced a success by Mr. J. S. Pickering in "The Surveyor" some time ago. He states that a tar macadam road can be made complete for about 46 cents per square yard, with 3 inches of macadam as a foundation and 1½ inches of chippings as a top surface. The price stated includes the cost of material, cartage, heating and tarring material, removing old macadam, laying and steam rolling.

Fall of the Campanile of St. Mark's, Venice.

Abstract of a paper presented to the Royal Institution of British Architects, by Luca Beltrami, Director for the Conservation of Monuments in Lombardy.

The fall of a monument of such exceptional importance as the Campanile of St. Mark's, Venice, could not fail to produce a vivid and painful impression on all sides, owing to its imposing mass, its intrinsic interest to artist and historian alike and the countless memories associated with an existence of over one thousand years. It is not difficult to understand, therefore, that its sudden disappearance has left a void to which the mind refuses to adapt itself, and people naturally desire some immediate explanation of the catastrophe, as though this might help them to accept with resignation an occurrence to which the imagination at first refuses credence. The very gravity of the disaster makes one hesitate to formulate the causes which led to it, with that precision which the general demand for a prompt explanation renders desirable. In order to define the main elements of the catastrophe and prepare the mind to form a full and exact conception of them, a careful study of the facts is required, and these cannot be fully known until the results of the inquiry now set on foot with a view to ascertaining, as far as possible, the causes of the unexpected collapse, are made public.

Though the early chroniclers are unable to agree as to the precise date of the foundation of the Campanile of St. Mark's, it seems probable that the work of construction was begun by Pietro Tribuno Memmo, who filled the post of Doge from 888 to 912. At this date excavations were made down to the stratum of clay found over large portions of the alluvial gravel of the Venetian lagoon. A footing was obtained in this clay by means of piles formed of tree-trunks, this pile-work being made to extend to the zone surrounding the foundations. On top of the piles was placed a *zatterone*, a solid raft-like structure consisting of a double layer of planks, and on this were erected the foundation walls, consisting of six courses of large stone blocks, of which the lowest course, resting on the *zatterone*, projected about 0.35 meter on every side for the purpose of increasing to some extent the area of the base.

These details, which we owe to the painstaking researches carried out in 1885 by Cav. Giacomo Boni, the architect at present in charge of the excavations in the Roman Forum, have discredited once and for all the old tradition, according to which the foundations of the Campanile are said to have been carried to a fabulous depth, with a consequent large increase in the area of the base. As a matter of fact, the foundations prove to have been out of all proportion to the remarkable height of the Campanile, the actual ratio being less than 1 to 20. This circumstance suggests the following questions: Was the total height—of 100.32 meters above the ancient level of the Piazza—to which the Campanile eventually attained, really the height contemplated by its builders when they fixed the depth of the foundations? Or was this height gradually added to, in the course of works which extended over six hundred years, until the superincumbent load came to exceed the limits which the foundations were able to support?

In endeavoring to answer these questions, we must first of all note the fact that, in spite of there being no records or drawings of the original plan, we are driven to the conclusion that the height originally contemplated by the builders of the ninth century can have been but little lower than that which was eventually attained in the early part of the sixteenth century, and which remained unchanged until the last few days. As a matter of fact, the lower part of the Campanile, with its little angle windows following the course of the inclined planes leading to the upper portion, rose to a height of about 54 meters, a height which we may assume to have been in harmony with the plans used in laying out the foundations, for, since the base was 12.80 meters square, the height of the solid portion of the Campanile was little more than four times its breadth. Nor are we justified in assuming that when the work of construction was first put in hand there was any intention of adopting more squat proportions, since it is manifest that the idea was to add to the impression of slenderness by means of the pilasters, connected above by arches, on the four sides of the tower.

This height of 54 meters was not reached till the days of Domenico Morosini, who was Doge from 1148 to 1156, and whose portrait in the great Council Hall of the Ducal Palace serves to record the fact that "sub me admirandum opus campanilis S. Marci construitur." An offering of two hundred pounds, Venetian currency, made by one Ottone Baseggio in 1133 "in order that the tower may be completed," tends to confirm the supposition that it was about the middle of the twelfth century that the bell-tower was finished, although the belfry itself was still to be added.

This massive lower portion, with its internal inclined planes supported by pillars connected one with another by series of arches, was composed for the most part of bricks 0.08 meter in thickness, with sides 0.4 meter square, in imitation of the Roman brickwork, reinforced at the outer angles with a few courses of Istrian stone. It should, moreover, be noted that it was not long before this lower part of the building suffered injury. The fire which broke out in Venice during the massacre of the Candians in 976 extended as far as the base of the Campanile.

In the latter half of the twelfth century it was decided to add to the tower the *loggia* or belfry and the famous *coronamento cuspidale.* In regard to this part of the work we must assume that the original idea was not carried out in the building which has just perished. Undoubtedly an arched belfry must have been contemplated in the original plans; but the cusp was meant to rise directly above this belfry, in a conic or pyramidal form and not with a square base, and placed on top of a heavy attic, as was the case in the design afterwards adopted. The total height, therefore, originally intended was somewhat less than that actually attained in 1517. It ought properly to have been about 9 meters lower, this being the measurement of the almost solid mass, devoid of openings, which the builders insisted on interposing between the belfry and the heavy pyramidal roof—with a result which, as we now see, was questionable from both the technical and the æsthetic standpoint.

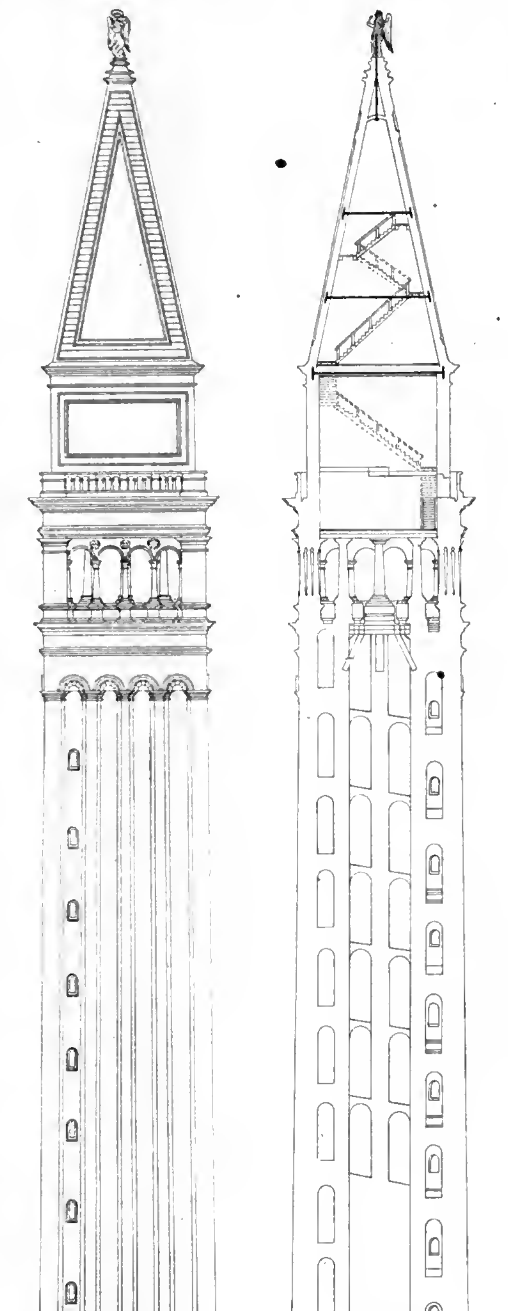
It was about 1173 that the first belfry was erected through the agency of Maestro Barattiero, but this must have been a somewhat unstable piece of work, since we find it had to be repaired or renewed in 1329 by Maestro Montagnana. From this date onwards the records are less scanty, and we read of various injuries sustained by the Campanile. In addition to others of which no record has been kept, there was a fire, close to the Campanile, during the festival at the accession of the Doge, Michel Steno, in 1400; in 1417 the woodwork of the roof was set on fire by lightning; in 1436 another conflagration destroyed the shops round the base of the Campanile. All these accidents must have inaugurated a condition of decay in various parts of the building, which was destined in the course of time to produce its results. In 1490 the belfry was again damaged by one of the numerous thunderbolts attracted by this great mass towering above the lagoon. It was, therefore, decided in 1510 to rebuild the *loggia* in a more substantial form. The records tell us that the task was entrusted to a certain Maestro Buono, but an earthquake interrupted the work and prevented the bells from being rung for several days. In 1514 both the heavy attic and the pyramidal roof were at last completed, and in 1517 the revolving statue of the Angel Gabriel, a lily in its left hand, its right raised in the act of benediction, attracted the eyes of all who sought to learn the direction of the wind. Thus more than six centuries had passed before the original purpose of Pietro Tribuno Memmo was realized.

It is scarcely a matter for surprise that, in planning a total additional height of 44 meters from the floor of the belfry to the head of the angel, the builders should have omitted to take into account the limits of resistance possessed by the foundations, when we remember that a tradition fortified by the lapse of centuries asserted that the foundations had been carried down to a fabulous depth. Moreover, the lower part of the tower, although it had been in existence for hundreds of years, showed but little deterioration, with the exception of a slight subsidence of but little importance compared with that of other less daring structures in Venice. This, too, in spite of the fact that the roof added in the early part of the sixteenth century had raised the load on the foundations to the not inconsiderable figure of 6 kilogrammes per square centimeter of their total area, about 6 tons per square foot.

It should be added that this important addition to the height of the Campanile had the effect of exposing it to much greater risks from electrical discharges. In 1548, 1565, 1656, 1745, 1761 and 1762, lightning wrought havoc on its mass of masonry. A remedy for this was found in the lightning-conductor fixed on the tower by Toaldo in the year 1776, but, unfortunately, this was subsequent to the thunderbolt of April 23, 1745, which wrought greater damage to the Campanile than it had ever before sustained, causing no less than thirty-seven fissures, the repair of which, though carried out with insufficient thoroughness, involved an expenditure of 8,000 gold ducats.

These various circumstances must not be lost sight of in any attempt to trace the causes of the catastrophe of the 14th of July last. The mass of masonry, erected without any special precautions in the way of binding the materials together, exposed as it was to unusual pressure, and shaken by thunderbolts and earthquakes, must have undergone a slow but continuous process of disintegration in its general structure, and of actual fracture in some places, with the result that it was reduced to a condition of precarious stability. This is the first conclusion with which we are confronted, and it would by itself serve to explain the sudden catastrophe that has occurred. Nor need we believe that the causes of this catastrophe are even partly to be sought for in the foundations, even admitting that these may have been disproportionate to the mass which they so long supported. Had there been any kind of movement in the foundations, it would have been evidenced by a disturbance of equilibrium in the building before and during the catastrophe itself: whereas the *insaccamento* of the *débris* and their minute disintegration lead one to believe that the masonry, already affected by serious general decay, had become, as it were, devoid of all power of resistance, and thus readily lent itself to a reopening of the old wounds of 1745. And here we come face to face with the question as to how far the recent catastrophe might have been avoided, retarded, or minimized.

In order to reply to these questions, it would be necessary to know the exact condition of the Campanile during the ultimate phase of its



The Campanile of St. Mark's.

existence—*i. e.*, from the instant when the movement which eventually led to its downfall first became apparent. The extreme brevity of this ultimate phase (three days, nineteen hours), and the complete collapse of the whole mass, prevented and still prevents us from obtaining the data necessary to reconstruct the history of this phase and draw the necessary deductions therefrom. An inquiry has been promptly opened by the Minister of Public Instruction, and the committee assembled at Venice shortly after the disaster. The committee of inquiry may, perhaps, succeed in collecting enough facts to enable them to trace the development of the catastrophe, and throw light on what may have been its most probable immediate cause. In the meantime we must content ourselves with the few data at present known and sufficiently authenticated. In the first place it will be of interest to remember that for some years past considerable apprehension has been felt in regard to the stability of the Campanile. We must not, however, attach undue importance to pronouncements which, since the disaster, have been and will doubtless continue to be published by persons who imagine that they can now claim credit for having foreseen its downfall all along. These prophets confined themselves for the most part to the expression of fears based on mere impressions and totally unsupported by any profound knowledge of the actual condition of the monument. A proof of this may be found in the fact that no specific proposal accompanied any of their prophecies, while the utmost that those who possessed a first-hand knowledge of the actual state of the monument could have done in the way of sounding a reasonable and effectual alarm would have amounted to some such warning as this: "The Campanile of St. Mark's was built at various periods of time, from various materials, by various processes. After standing for centuries it is now in a dangerous condition, and your first duty above all others is to avoid any innovation or meddling which may tend to aggravate its precarious state." This was the essential condition on which a prolongation—though not an indefinite prolongation—of its precarious condition might be hoped for.

Actual measures of general restoration did not appear to be so easily advisable. In fact, even if men had realized how far the general decay of the walls had progressed, it would not have been a case of pronouncing on the probable result of clamping with iron girders or even on the effect of underpinning, since neither the one nor the other would have proved efficacious or even advisable, except in dealing with defects confined to special parts of the whole mass, or in case it had been found necessary to restore certain definite portions of the building. In other words, even if the catastrophe had not been so sudden, it would have been very difficult—if not altogether impossible—to devise or adopt any measures which would have proved truly radical and efficacious. By this I do not wish to imply that the condition of the Campanile should have been viewed with fatalistic indifference, or that we ought to have awaited with resignation the moment of its downfall. For instance, there was one fissure, which, though insignificant in appearance, and therefore treated as of little consequence, suddenly became very serious and proved to be one of the determining factors in the final catastrophe. It will be remembered that there were close to the corners of the Campanile—to be precise, along the left side of each of its internal walls—a series of small windows which served to light the various inclines leading to the belfry, there being one window to each of the landings forming the turnings of the inclines. These small windows, of which there were eight on each side of the Campanile, were very happily arranged in so far as the purpose of giving light to the various parts of the inclines was concerned, but occurring, as they did, in close proximity to the corners of the tower, they constituted an effective source of weakness. It will be readily understood, therefore, that a crack which began at the lower window on one of the sides of the Campanile and extended as far as the last window but one, thus placing the various window openings in communication with one another, meant a very extensive solution of continuity—and this in a vertical direction—between two of the faces of the Campanile.

As luck would have it, this fissure, which was not very alarming in appearance, and from the nature of the case did not extend very rapidly, was not kept under proper observation by those responsible for the good preservation of the monument. In fact it is barely five years since the Board for the Preservation of Venetian Monuments—its attention having been called to the intrinsic, if not apparent, gravity of this fissure—took occasion to publish in its Annual Report the following note—a note which illustrates better than any words of mine its light-hearted method of dealing with the apprehensions then expressed: "One of the usual rumors whispers that the Campanile of St. Mark's must inevitably fall down, because some portions of the old wall have been picked up in the caretaker's rooms, the said portions being attributed to the extension of a crack. Now the caretaker's dwelling has been in its present state for about a century, as may be seen from the drawing by Cicognara (in his *Fabbriche più cospicue di Venezia*), and the fissure appears just as it is now in very early photographs of the Campanile; in other words, there has been no sign of this terrible extension of the fissure for many years." The choice of the factors on which this conclusion is based is sufficiently primitive! As a matter of fact, the moment the necessity or opportunity arose for silencing the voice of the alarmist, the Board, which has its offices within a few yards of the Campanile, ought to have made inquiry and published to the world the nature of the fissure which had given rise to anxiety, instead of contenting itself by quoting the authority of a picture which left the hands of the frame-maker a hundred years ago, and referring to an old photograph of half a century back. Still more strange appears the argument that because a crack has been in existence for a hundred years without any sign of increasing it is therefore to be regarded as harmless. As though the natural decay due to the lapse of time, and the unforeseen yet not impossible changes due to subsidence, shock or other causes, did not in themselves furnish good reason for refusing to adopt thus readily a conclusion of such a fatalistic nature.

A more prudent attitude in regard to this crack would have sufficed, and the adoption of some precautionary measure—such as the filling in of the windows situated on the line of fissure, in order to restore the solidarity of the two external walls of the Campanile that had become detached, and to prevent any change, however slight, in the general conditions of the building, due perhaps to some ill-considered innovation, or even to circumstances of a purely fortuitous and unforeseen character—would have put an end to that widening of the injury which in two days became threatening, on the third day showed that the evil was beyond remedy, and within the brief space of ninety hours led to a catastrophe. For while the defects observed in structures which have to withstand not only the purely static action of weights exercising pressure in a vertical direction, but also the dynamic effect of the thrust of arches or vaultings, may be a source of alarm from the moment of their appearance owing to their manifestly progressive character, it by no means follows that defects in structures which are not called upon to withstand any such thrusting action—as in the case of the Campanile of St. Mark's—should not be regarded with apprehension. For though they may not present those progressive characteristics which call for immediate remedial measures, they indicate none the less surely a condition of unstable equilibrium in the monument; and a day must come when some seemingly trivial cause proves sufficient to determine a catastrophe, and finds the general structure predisposed to second the first movement and aggravate it with phenomenal rapidity.

This was the case with the Campanile of St. Mark's. The determining factor in the catastrophe must, of a surety, have been some circumstance of trivial importance compared with the final effect produced, but this does not lessen the culpability and shortsightedness of those responsible. The recriminations which have accumulated during the last few days in the Venetian newspapers and in the interviews with persons more or less compromised by the disaster make one reluctant to enter on a more detailed examination of the catastrophe while an inquiry is still pending. There is, however, one inference which may fairly be drawn from the facts before us. The very multiplicity of the accusations and disclaimers and the eagerness with which responsibility is denied are in themselves conclusive evidence of the disorganization and inefficiency of those responsible for the preservation of monuments in Italy. For years past every one in Venice has been familiar with the endless antagonisms, friction, rivalry, and quarreling between the persons charged with the maintenance of the more important monuments. For years past they have witnessed the continual iteration of charges, impeachments and alarms. Time after time have ministerial committees intervened to put things right, with invariably illusory results. It is the men rather than the monuments who play the leading part in these disputes.

[Note.—The drawings accompanying this article are from Cicognara's "Fabbriche e i Monumenti cospicui di Venezia," published in 1838-40.]

Boiler Rivets should be carefully examined, according to a report of the Mutual Boiler Insurance Company, by the following cold tests; driving them down on an anvil with the head in a die, by nicking and bending back on themselves without developing serious cracks. In tests made by the company, steel rivets stood up well as a rule, but iron rivets did not and one brand of steel rivets proved very poor.

The Waste of Water in Washington is becoming a more serious matter than ever before, owing to the additional cost which filtration will soon impose on the management of the works and the need of constructing a new conduit very soon if the present rate of consumption is maintained. The supply is now about 193 gallons per capita daily, or double the amount there is any reason whatever for furnishing to a community so largely residential. Colonel Miller, who is in charge of the Washington aqueduct, draws special attention to this condition in his last report, but does not seem particularly hopeful that the only positive remedy, the use of meters, will be adopted very soon. It is difficult to understand why the people of Washington, who are noted for their complaints about high taxes, should oppose so bitterly this equitable means for reducing in no small way the cost of such an important article as water.

Water Supply System in the Maiden Lane Building, New York.

An eighteen-story steel-cage office building has just been finished with a front of 75 feet on Broadway and 110 feet on Maiden Lane. It is shaped like an irregular U in plan, with a 28x38-foot central light court and a smaller one at the side, as indicated in the typical floor plan. The water supply is received through a 4-inch service pipe from the Broadway and a 3-inch one from the Maiden Lane city mains. It is not filtered but is taken direct through a fish trap, by-passed meter, gate valves 4-inch pipe and two ball cocks, to a rectangular 2,000-gallon suction tank, made of ¼-inch steel with a ⅛-inch steel cover and a hinged door 2 feet square over the ball cocks.

A Lewis steam pump is installed for house and fire service and its 4-inch suction pipe is connected directly to the bottom of the tank. It is cross-connected to a special pump for the safe-lifting elevator, but is not connected to the boiler feed pumps. Its discharge riser delivers without a hush pipe through ball cocks in the 3,500-gallon steel roof tank, which is similar to the suction tank. The roof tank is provided with the usual safe, overflow and emptying pipes, and has a float which indicates the height of water on an engine-room index. It has a pressure pipe connected with a Ford regulating valve which controls the steam supply to the house pump and starts and stops it when the water in the tank reaches the limiting low and high levels.

The pump also delivers directly into the fire line, a 6-inch stand-pipe near the center of the building, which is connected at the upper end with the roof tank and has a 2½-inch valve and 100 feet of linen hose in the corridor of every story. A branch runs to the sidewalk and terminates there with a siamese coupling for fire engines. Check valves are set at the top and bottom of the stand pipe and next to the siamese coupling so that the fire pressure can not escape into the tank or house mains or back up on the pumps.

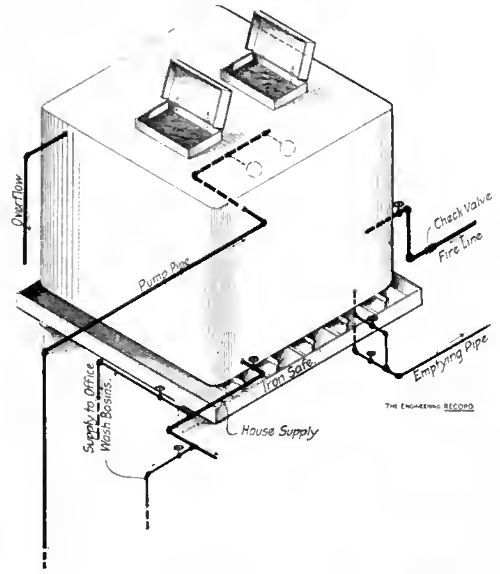
The 3-inch supply from the roof tank has a vertical 2-inch branch to the cellar, but its main connections are to the branches of a horizontal distribution main run in a U-shape parallel with the corridors above the suspended ceiling of the eighteenth story. This main provides for a down supply to all the cold water fixtures above the first story. It has ten 1½-inch risers to supply the vertical groups of office wash basins, the slop sinks and the toilet rooms above the first story. A 2-inch supply to the cellar has a branch to the hot-water tank and another to a header from which valved lines are run on the cellar ceiling to supply the fixtures in the basement and first story. The header is cross-connected with the street pressure supply to the boiler feed pumps, but is generally operated under tank pressure.

The hot-water tank is a ¼-inch horizontal steel cylinder 3 feet in diameter and 6 feet long. It is covered with asbestos and canvas and is suspended from the basement floor-beams. It was tested at the factory to 100 pounds pressure and contains an 80-foot coil of 2-inch galvanized iron steam pipe. Steam at the regular boiler pressure of about 125 pounds is admitted to the coil through a Davis thermostat set to shut it off automatically when the temperature of the water in the tank rises to 130 degrees. The hot-water outlet connects with a header from which five branches are run on the basement ceiling. One of them rises to the attic and supplies slop sinks, toilet-room wash basins and a private bath room; the others supply the fixtures in the first story and basement. All of them have return circulation pipes connected to the cold water inlet for the tank.

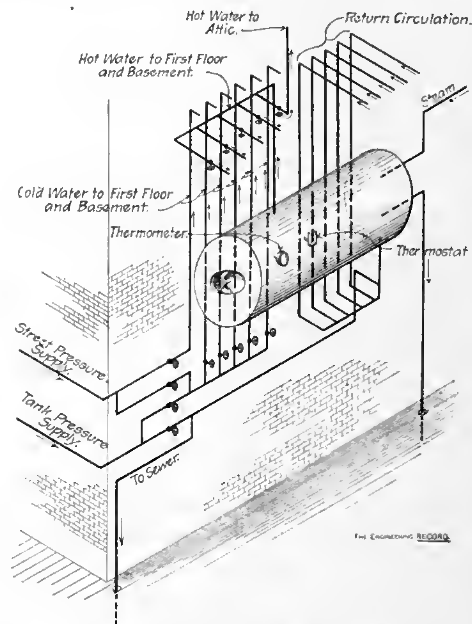
All of the cold-water supplies to the basement and first story and all of the hot-water supplies are valved near the hot water tank and the whole system can there be emptied into the sewer, but the different riser and distribution lines are not provided with separate emptying pipes. The wash-basin cold-water supplies from the attic distribution line terminate at the bottom with a reverse bend, and the short leg forms an air chamber about 3 feet high. These lines can be emptied through their lowest fixtures, but have no emptying valves or waste pipes. The exposed pipes at wash basins and in the toilet rooms are of brass, nickel plated; all other water pipes are of galvanized wrought iron or steel, standard weight, with cast and malleable iron beaded fittings. The ceiling pipes in the cellar and attic and the hot-water pipes throughout the building are protected by felt or asbestos insulation ½-inch thick and covered with canvas.

There are Chapman, Crane or Fairbanks gate valves on the hot and cold water supplies to all the toilet rooms, office basins and slop sinks, and all fixtures have air chambers. The branches to each fixture have angle valves of a special make with a key-handle engaging the valve stem inside a protecting socket so that they can be operated only by the engineer's wrench. They are carefully adjusted so as to throttle the pressure in the lower stories and reduce the flow through the faucets. There is a Pratt & Cady swinging check valve set in the return circulation header at the hot-water tank to prevent the cold-water supply from backing up in it.

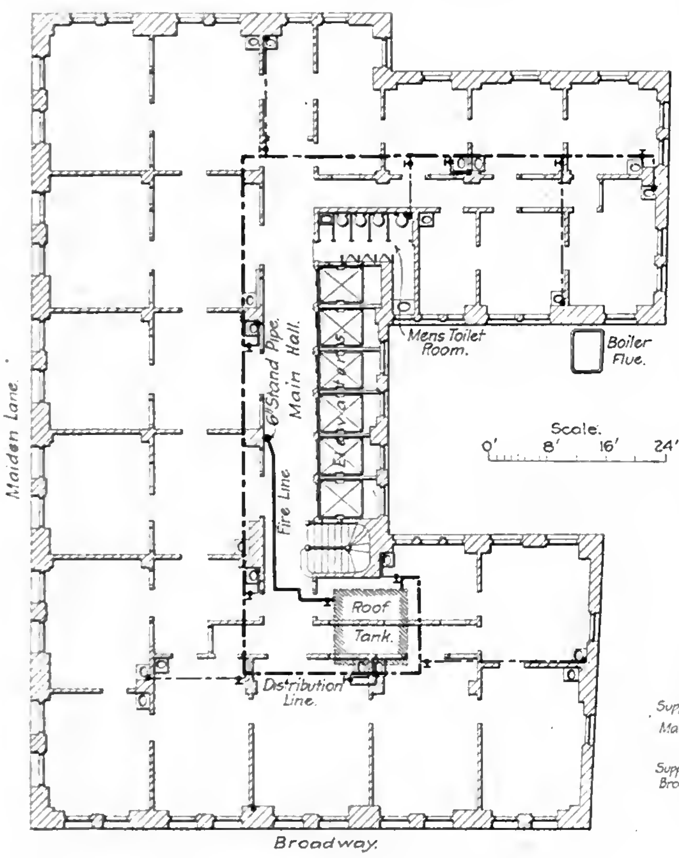
All the water pipes are carefully laid to grade to prevent the formation of air pockets and both hot and cold riser lines are vented from the highest point to the roof tank by pipes not seen in the general diagram. The cold-water risers are rigidly connected to the floorbeams, but the attic hot-water riser is divided into three sections by two horizontal expansion loops and is supported only at the middle points of these three sections. The average total daily consumption of water, in summer, is about 37,500 gallons including the supply to one of the three 300-horse-power boilers, which suffices to operate the plant when no steam heat and little electric light is required.



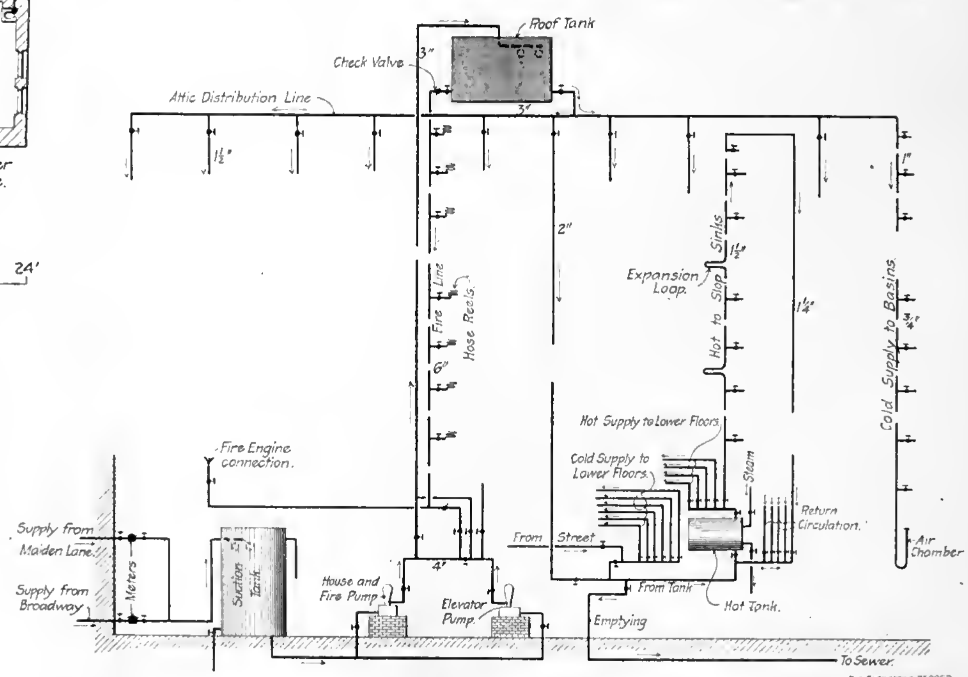
Roof Tank.



Hot-Water Tank Connections.



Typical Floor Plan, Maiden Lane Building.



General Diagram of Water Piping, Maiden Lane Building.

The office partitions are of course varied to suit tenants and in some cases the wash basins shown in the typical floor plan are omitted or are located in different places, and in the bank on the first floor there is a special toilet room for employees. One of the upper floors is occupied by the Broadway Building Company and here there is a private bathroom handsomely finished with white marble and plate glass and containing a porcelain bath tub and shower bath, a wash basin and closet. In the basement there is a café with kitchen plumbing, a barber's shop with hot and cold-water fixtures, and a public toilet room in the sidewalk vault. In the basement there is an engineer's toilet room with bath, closet and wash basins.

The toilet rooms have mosaic floor and tile wainscot 6 feet high with sanitary cove tile base board. The partitions are slabs of Tennessee marble 6 feet high which are set without standards, with cement joints on the floor. The doors have solid panels of polished oak and are mounted on spring hinges. The slop sink is set in an ante room which communicates with the toilet room through double swing spring half doors without latches.

Messrs. Clinton & Russell were the architects of the building and Col. J. H. Wells, of their staff, was the engineer. The George A. Fuller Company was the general contractor and Mr. D. M. Quay was in charge of the sanitary work. Messrs. Wells & Newton were subcontractors for the plumbing, of which Mr. J. E. Flynn was foreman.

A 440-Volt Plant will be installed for lighting the five new buildings of the University of Illinois at Champaign. Two-phase alternating current will be used, and each phase will be treated as a single-phase circuit operated on the three-wire system, the neutral wire being supplied with current from an auto-transformer. Although the 220-volt lamp is somewhat less efficient than the 110-volt lamp, the difference is expected to be of very little moment in this case, since the exhaust from the steam engine plant operating the generators is to be used in heating the buildings. The generating station contains two belted two-phase generators, one of 50 and one of 75 kilowatts, operated at 440 volts, to which will shortly be added an engine-type, revolving field, 120-kilowatt alternator, purchased from the Westinghouse Electric & Manufacturing Company.

The Selection of Gas Engines.

By J. D. Lyon.

Although gas engines of both the two and four cycle types are made and operated in this country, the great predominance of the four cycle poppet valve gas engine at the present time no doubt simplifies the matter of gas engine selection very materially, but beyond the question of type there are a number of other considerations which should be taken into account in order to obtain satisfactory results in any given case. One of the first and most important considerations should be to secure an engine suited to its work, and this seems to be a point frequently overlooked by users and ignored by manufacturers.

Buyers of steam engines usually decide upon the class of engine especially adapted to the requirements of the plant to be operated before asking for proposals from manufacturers, and as a rule the specifications are so worded as to prevent useless waste of time in considering proposals on engines not belonging to the class decided upon. Of the various general forms employed in steam engine construction, each is intended to render the engine a little better adapted to some particular class of requirements and there is no valid reason why the same should not be true of the gas engine. There are, no doubt, cases in which a high speed gas engine will fill the conditions better than one of slow speed, for instance, in a case of a basement electric plant, in which space is valuable and more than offsets the disadvantages inherent to high speed engines (no reflection upon this valuable class of engines is intended). Now the fact that this engine has proved the best possible selection for the plant in question does not indicate that it would be in every case as good for work of some other description, as, for instance, in a manufacturing plant in which skilled attendance is at a premium and the work is of rough and heavy character, subjecting the engine to severe shocks and strains.

By a course of natural selection the Corliss and other heavy duty slow speed steam engines have come to be used almost exclusively for a certain class of work, the lighter, higher speed automatic engine for another class, and the plain slide valve engine fills all the requirements of many users. This same process of selection will, probably, divide the various forms of gas engines into classes, which will become well known to users, and the result is likely to increase the reliability and enhance the reputation of the gas engine, especially for use in plants of considerable importance. At the present time, however, almost every builder of gas engines recommends the engine of his manufacture for power uses of any description, and while it is no doubt true that the engine will furnish power for almost any class of work, the fact remains that each type of engine will be found better adapted to certain kinds of work.

This renders it advisable for the prospective customer, who is without mechanical training, to secure the services of a competent engineer to aid him in the selection of a gas engine for any plant which requires a considerable amount of power, and the engineer's fees will be found to be a part of the investment which is likely to return the greatest dividends. A careful reading of the catalogues of various builders cannot but result in confusion of the mind of the man who is obliged to secure all his information on the subject from this source, since statements are frequently made in one catalogue which will be found flatly contradicted in another. It is probable that the writers of such statements are not intentionally guilty of attempting to mislead the reader, but that statements which are merely expressions of opinions or prejudices are given as facts.

There are certain main features which should be taken into account in forming a decision as to the form or class of engine which is most desirable for any given work, and these can only be arrived at by a careful consideration of the particular details of each case. There are, however, some points which apply very generally to gas engines as a class, and a few suggestions to the prospective user, or the engineer who finds himself called upon to assist some client in the selection of a gas engine, may be of value,

First of all it is advisable to examine a number of machines of the general form decided upon, and note carefully the manner in which they are doing their work, and this is a suggestion which, naturally, would occur to any one who had such matters to decide. A pleasing outline in the design of the engine should always be expected in a machine which has been designed by a really capable man. Sharp angles should not be of frequent occurrence in the castings, and all parts under strain should have large well rounded fillets at all such angles. The manner in which the main bearings are made, and in which they are adjustable, should be very carefully considered, as the bearings of the gas engine seem to give more trouble than those of the steam engine. They should not only be easily adjustable, but the metal with which they are lined should be so placed as to render the replacing of the lining easy. The crank shaft should be heavy enough so that the rim of the fly-wheel does not show any marked tremor or vibration at the time of explosion of the charge in the cylinder. In most cases accessibility of working parts should be a point to be given a good deal of importance. The auxiliary mechanism should be driven in such a manner as to reduce wear on gears and cams to a minimum, and should present no appearance of trappiness. The larger castings should have no small projections cast integral with them, and such parts as are necessary to be fastened on the larger castings should be bolted in place. An important point in connection with the valve mechanism is the manner in which the valves are lifted from their seats, especially the exhaust valve, which is exposed to the high temperature of the exhaust gases. This lift should be as nearly as possible in a straight line with the axis of the valve stem, since an uneven wear on the guides of the valve stems will invariably result in leakage of the exhaust gases past the valve stem, causing much annoyance from sticking of the valves. In engines of any considerable size these guides should be made in the form of a removable bushing, which can be replaced when it becomes worn to the extent of leakage. The ignitor should be of as simple construction as possible, and should always be made so as to produce ignition of the charge at the proper point in the cycle of the engine and to admit of an easy regulation of this point of ignition.

It is always well to inquire as to the cost of maintaining the ignition on any engine under examination, since this is one of the most important, and at the same time one of the most troublesome details in the gas engine. The parts of the ignitor should be strong, and so designed as to allow new parts to be very easily put in place, without extra work of fitting.

The combustion chamber should always be of such form as to present the largest volume with the smallest surface, and this surface should not be broken up by angles and pockets to any great extent. The larger the surface surrounding the combustion chamber the greater the loss of heat to the cooling water. The effect of breaking the combustion chamber up into distinct spaces connected by more or less restricted passages is to retard combustion with a serious loss of efficiency.

The water jackets should, of course, surround the cylinder head, cylinder, and as much as possible of the exhaust valve stem. The seat of the exhaust valve should be so arranged as to permit of easy renewal in engines of any considerable size.

A great diversity of opinion exists as to the best method of connecting cylinders on horizontal engines to their frames. The same is also true of a great many of the details in connection with the engine, but the suggestions given above may be applied equally well to any type, since the same general conditions hold good in all. There are, no doubt, many other features, which would be well worthy of careful consideration. Upon these the prospective user should form his judgment from a careful examination of plants in use, and a judicious questioning of the users.

Trade Publications.

The Hayden & Derby Mfg. Co., 85 Liberty St., New York, is interested exclusively in making injectors, ejectors and jet apparatus. It has issued a new catalogue describing its line, which is particularly explicit in the portions relating to automatic and double-tube injectors. The method of selecting the proper type and size for a given service is explained, and there are useful suggestions concerning the causes that may injuriously affect the operation of an injector.

A valuable explanation of the appliances used in the transmission of power by wire rope, the selection of a plant for a given service and the method of erecting it, is given in a book prepared by the John A. Roebling's Sons Co., Trenton, N. J. There are a number of useful tables of the horse-power transmitted under different conditions and of the properties of rope used for this purpose, together with many illustrations and brief descriptions of installations.

The United States Wood Preserving Co., 29 Broadway, New York, has issued a pamphlet by Mr. F. A. Kummer describing the advantages of creo-resinate wood pavements. The blocks treated by this company's process have now been in use long enough to demonstrate their resistance to wear and their effect on horses, subjects which are discussed in the pamphlet in a number of letters.

The Hunt system of industrial railways for shops and factories is well known, but in case a reader unacquainted with its peculiarities is desirous of obtaining a general understanding of them, he will find the information given pictorially in a pamphlet of views taken in a number of famous shops, just issued by the C. W. Hunt Co., Allen St., West New Brighton, N. Y.

The new bulletins of the Fort Wayne Electric Works, Fort Wayne, Ind., are as follows: No. 1,025, direct-current belted generators with capacities of 20 to 400 kilowatts and various speeds; No. 1,030, single-phase generators in capacities from 37½ to 300 kilowatts at 60 cycles and 33 to 400 kilowatts at 140 cycles; No. 1,032, direct-current belted motors for slow, medium and moderate speeds and rated at 25 to 105 horse-power. All the bulletins are finely illustrated and contain full tables of the dimensions and capacities of the apparatus described.

The Keystone Valve & Mfg. Co., 2626 Carson St., Pittsburg, has prepared a catalogue of straight-way, three-way, four-way and locomotive blow-off valves designed specially for hydraulic and compressed air service, boiler blow-offs and like uses. A quarter turn of the operating lever gives a full opening of the valve.

The H. W. Johns-Manville Co., New York, has issued a pamphlet concerning the Manville fire extinguisher. This is a tube filled with a powder which, when sprinkled on the base of a fire, generates carbon di-oxide and thus extinguishes or checks the flames.

Personal Notes.

Mr. G. H. Stevenson has been reappointed city engineer of Lafayette, Ind., for a term of two years.

Mr. R. M. Ellis has resigned his position as superintendent of the Vicksburg, Miss., Electric railway to become superintendent of the Natchez, Miss., Electric Railway Co., and Mr. Walter Mattingly has been appointed to succeed him.

Mr. Howard L. Ingersoll has been transferred to the Middle Division of the New York Central & Hudson River Railroad as resident engineer and Mr. Wm. T. Dorrance has been appointed acting resident engineer of the Eastern Division.

The following candidates for different grades of membership in the American Society of Civil Engineers were announced elected September 3: Members—W. E. Angier, resident engineer, Southern Illinois & Missouri Bridge Co., Thebes, Ill.; F. T. Bancroft, Joy & Bancroft, Detroit; O. W. Childs, chief engineer, Stupp Bros. Bridge & Iron Co., St. Louis; F. W. Cohen, engineer of erection, Pennsylvania Steel Co., Harrisburg, Pa.; S. E. Coombs, chief engineer, Southern Missouri & Arkansas and Cape Girardeau & Northern Railroad, Cape Girardeau, Mo.; W. W. Crehore, Structural Engineering Co., New York City; G. M. Eldridge, superintendent, Tampa Water-Works Co., Tampa, Fla.; Elliot Holbrook, chief engineer, Kansas City Southern Ry., Kansas City, Mo.; E. T. E. Lansing, city engineer, Little Falls, N. Y.; W. N. McDonald, assistant engineer, Dept. of Streets, Havana, Cuba; O. M. Eidlitz, New York City; H. A. E. C. von Schon, Sault Ste. Marie, Mich. Associate members—R. I. D. Ashbridge, first assistant engineer, Improvement, Extension and Filtration of Water Supply, Philadelphia; M. C. Bland, contract manager, American Bridge Co., Cleveland, O.; Abraham Gideon, assistant engineer, Dept. of Sewers, Havana, Cuba; J. T. Henderson, assistant engineer, Connecticut River Bridge & Highway Comm., Hartford, Conn.; F. D. Hughes, assistant engineer, Midland Bridge Co., Kansas City, Mo.; G. A. Noska, assistant engineer to George B. Post, New York City; H. VB. Osbourn, assistant engineer, Improvement, Extension and Filtration of the Water-Supply, Philadelphia; J. G. Peck, bridge engineer, State Engineer's office, Albany, N. Y.; E. E. Pettee, with J. R. Worcester, Newtonville, Mass.; J. W. Rickey, engineer, St. Anthony Falls Water-Power Co., Minneapolis, Minn.; L. J. Riegler, with Pennsylvania Co., Allegheny, Pa.; G. T. Roberts, assistant engineer, Bureau of Engineering, Buffalo, N. Y.; F. N. Sanders, assistant engineer, State Engineer's office, Albany, N. Y.; M. H. Wright, roadmaster, Louisville & Nashville R. R., Nashville, Tenn.; G. C. Bartram, Boston, Mass. Juniors.—F. L. C. Bond, New York City; H. G. Burrowes, Brooklyn, N. Y.; W. S. Getchell, Denver; R. A. McCulloch, Orange, N. J.; Rudolph Quanz, West Hoboken, N. J.; C. L. Richardson, New York City; A. L. True, Portland, Me.

The Society of German Engineers had 16,159 members at the end of 1901, according to a recent report. Its weekly journal, the "Zeitschrift," had about 1,800 pages during the year, and the contributions sent to the editor were far more numerous than the limits of the publication could accommodate. The directors report that they have arranged for the writing of a treatise on the steam engine and another on its history.

The New England Water-Works Association will hold its twenty-first annual convention at the Hotel Brunswick, Boston, Sept. 10, 11 and 12. The papers and addresses are as follows: "Duties of Municipalities Regarding Water Supplies," by Hon. J. O. Hall, Quincy; report of committee on "Standard Specifications for Cast-Iron Pipe," Mr. Freeman C. Coffin, chairman; a talk with lantern slides on recent work done by the Metropolitan Water and Sewerage Board, Mr. F. P. Stearns; "The Water Supply of Nashua," by Mr. Horace G. Holden; report of the committee on the "Apportionment of Charges for Private Fire Protection, and the Means of Controlling the Supply Thereto," Mr. Byron I. Cook, chairman; "A New Turbidimeter," by Mr. Charles Anthony, Jr.; "The Removal of Color and Odor from Water," by Mr. H. W. Clark; "The Physical Properties of Water," by Mr. Allen Hazen; report of the committee on "Uniform Statistics," Mr. Joseph E. Beals, chairman; "Recent Investigations in Purification Methods," by Prof. L. P. Kinnicutt; "What an Engineer Saw in Venice," by Mr. Desmond FitzGerald; "Twenty Years After—a Retrospect," by Mr. R. C. P. Coggeshall.

Dampness in Masonry Vaults in fortifications is a source of frequent and serious trouble. In a battery at Pensacola the electric plant is under one of the gun platforms and was continually wet during inclement weather. The remedy adopted at this place has been described as follows by Lieut. Lewis H. Rand, Corps of Engineers, in local charge of the work: To remedy dampness in dynamo and storage-battery rooms, an oil coating was applied to the gun platform under which they are. An asphalt coating would be cut to pieces by the wheels of the ammunition trucks. A mixture of resin and boiled linseed oil in the proportion of 1 to 3 was applied. The platform was first carefully swept and cleaned; then clay forms one-half inch high were constructed by laying 1½-inch planks in the desired positions and building up against their edge the dampened clay to a thickness of about 3 inches; after the clay had dried and hardened the planks were removed. Diagonal rectangles, in checkerboard style of about 36 square yards each, were first treated. Twenty gallons of the mixture in a 55-gallon caldron were heated to a point such that the mixture was just short of boiling over, when it was poured out on the rectangle and spread with brooms to cover the entire surface. Warm, clear weather in a dry spell, so that the concrete might be as dry and absorbent as possible, was chosen for the work. After standing 24 hours the forms were removed and replaced for the uncoated rectangles with a lap of about 12 inches. After these were taken up the laps were again given a thin coating, simply poured on, as was also done to the steps and other irregular places where forms could not be constructed. After standing for some two weeks the thick unabsorbed resin was scraped off. The improvement in the dynamo room has been very noticeable, although the dripping water is not completely stopped. A coating was given over about 170 square yards at a total cost of about $70, and using altogether about 75 gallons of linseed oil and 25 of resin oil.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see page xv, xvii, xviii and xxvii.

WATER.

South McAlester, Ind. Ter.—Engr. Chester B. A. Davis, 10 Wall St., New York, N. Y., with branch office at San Antonio, Tex., writes that the estimate of cost of proposed water works is $194,000 and for a sewerage system $50,000. Bonds are yet to be voted.

Philadelphia, Pa.—Bids will be received by the Dept. of Pub. Wks., Bureau of Water, until Sept. 23, for preliminary filters for the lower Roxborough Station. Wm. C. Haddock, Dir.

Pierce, Neb.—Bids will be received by L. R. Hertert, Village Clk., until Sept. 16 for a steel tank, 22 ft. in diameter and 30 ft. high, with a conical steel roof and hemispherical bottom, on a steel tower 80 ft. high, with concrete foundations. Arnold C. Keonig, Engr., N. Y. Life Bldg., Omaha, Neb.

El Paso, Tex.—Bids will be received until Oct. 22 by J. A. Escajeda, City Clk., for supplying the city and its inhabitants with water for a period of 35 years; said water to be obtained from the "Mesa," near Ft. Bliss Military Reservation, near El Paso.

Golden, Colo.—Bids are wanted Sept. 15 for constructing a gravity system of water works. W. H. Carter, City Clk.

Matagorda, Tex.—Engr. Chester B. Davis, 10 Wall St., New York, N. Y., with a branch office at San Antonio, Tex., writes that a pumping plant will soon be required for rice irrigating works; capacity, 60,000 gals. per min., 30-ft. lift; water to be taken from the Colorado River in Matagorda Co., Tex.; initial area to be irrigated, 8,000 acres; ultimate area, 75,000 acres; estimated cost, $225,000.

Coeur d'Alene, Idaho.—The water works and electric light plant owned by Clem King, of Couer d' Alene, and Jas. Monaghan, of Spokane, Wash., are stated to have been destroyed by fire Aug. 26.

Lexington, Mass.—A press report states that a committee of 5 has been appointed to investigate the advisability of introducing the metropolitan system into the town to replace the present supply.

Pauls Valley, Ind. Ter.—Engr. Chester B. A. Davis, 10 Wall St., N. Y. City, N. Y., writes that the estimated cost of the proposed water works is $65,000. Part of the bonds have been authorized and the work of sinking a deep well will be contracted for in about 3 weeks. Contracts for the rest of the work may be held back until results of the well test are known.

Laramie, Wyo.—The Red Lands Ditch Co. has been incorporated, with a capital of $8,000, by John Clifton, Novia S. Beavers and others, to build an irrigation canal 13 miles long to take water from Sheep Creek, a tributary of the Little Medicine River. The company will have its general offices at Laramie and Little Medicine.

Tabor, Ia.—J. J. Dunnegan, of Shenandoah, is reported to have secured the contract for constructing water works here, for $6,000.

Glenwood, Pa.—A press report states that the Baltimore & Ohio R. R. Co. will construct a water station at Glenwood, at a cost of $30,000. J. M. Graham, Ch. Engr., Baltimore, Md.

New Florence, Pa.—The New Florence Water Co. is reported incorporated, with a capital of $10,000. D. S. Hoover and W. W. Grove, of New Florence, are among the directors.

Whatcom, Wash.—K. Sarset is stated to have secured the contract for laying a new water main, for $7,000.

Edmonds, Wash.—The Edmonds Spring Water Co. is reported to have been formed, with a capital of $15,000.

Troy, N. Y.—Water works bonds amounting to $578,125 are stated to have been sold on Aug. 29.

Ft. Morgan, Colo.—The Town Clk. writes that the proposition to construct water works at a cost of $40,000 is under consideration.

Fayette, Ia.—The citizens are stated to have voted to issue bonds for water works.

Long Branch, N. J.—A press report states that the new Monmouth Water Co. has petitioned the Long Branch Comrs. for permission to incorporate the Home Water Co. for the purpose of laying pipes and doing business here.

Shelbina, Mo.—The proposition to issue water works bonds is reported to have carried at a recent election.

Shenandoah, Va.—The item appearing in last week's issue under Shenandoah, Pa , should have been Shenandoah, Va.

Hagerstown, Md.—It is stated that the Washington County Water Co., which supplies Hagerstown, will tap the Antietam Creek where the mains cross the stream. A pump with a daily capacity of 800,000 gals. will be put in at once.

Rockville, Md.—The Mayor and Council are stated to have decided to employ Engr. Fink, of Washington, D. C., to superintend the installation of the new pumping machinery for the two wells.

Kansas City, Mo.—It is stated that Wm. Goodwin, Supt. Water Dept., will recommend to the Bd. of Pub. Wks. an extension of the 16-in. water main in St. Louis Ave., a distance of about 2,800 ft., at a cost of about $6,000.

Lee, Ill.—The question of establishing water works is reported to be under consideration.

Geary, Okla. Ter.—The citizens are stated to have voted to issue $27,000 bonds for water works.

Livingston Manor, N. Y.—A press report states that the Livingston Manor Water Co. has under consideration the construction of a reservoir, near Marguerite Falls. W. H. Cowan, Pres., Montgomery, N. Y.

Cohoes, N. Y.—It is stated that about $40,000 will be expended in improving the water works.

Minneapolis, Minn.—The Custodis Chimney Co., of Chicago, Ill., is stated to have secured the contract for erecting a 200-ft. brick chimney 7½ ft. interior diameter, for the Northeast Minneapolis pumping station, at $9,247.

Toronto, Ont.—City Engr. Rust is stated to have recommended the installation of a 15,000,000-gal. pumping engine.

Oakland, Cal.—A press report states that the Com. of Five of the Water Supply will shortly proceed to make a thorough investigation of the water resources available for Oakland. Mr. Chamberlain is Chmn. of the Com.

Dallas, Tex.—Engr. Chester B. A. Davis, 10 Wall St., New York, N. Y., with branch office at San Antonio, writes that this city has just voted $100,000 bonds for water-works improvements, but it is probable contracts aggregating $150,000 or more may be entered into. A large portion of this will be expended in connecting the new impounding reservoir—capacity 1,000,000,000 gals.—with the settling basins and the pumping station; the remainder in improving and extending the distributing system. Plans not yet completed.

New Bremen, O.—A press report states that Engr. John P. Force, of Columbus, estimates the probable cost of water works for New Bremen at $27,000.

Grinnell, Ia.—Bids are wanted Sept. 12 by the Grinnell Water Co. for a power pump, cast-iron pipe, standpipe, etc., as advertised in The Engineering Record.

Weiser, Idaho.—Bids are wanted Oct. 3 for furnishing material for a water works and electric light system. Stewart H. Travis, City Clk.

Blairsville, Pa.—Bids will be received by E. M. Evans, Chmn. Water Com., until Sept. 12, for furnishing material and making improvements to the water work, as advertised in The Engineering Record.

Eden Valley, Minn.—Bids will be received by W. R. Salisbury, Village Recorder, until Sept. 27 for constructing water works.

Northampton, Mass.—Water works bonds amounting to $50,000 were sold Aug. 29.

Dallas, Ore.—H. V. Gates, of Hillsboro, is stated to have submitted a proposition to City Council to install and operate water works. He asks the city for a $12,000 bonus and a 20-year franchise.

Dickson, Tenn.—The citizens are stated to have voted Aug. 28 to issue $25,000 bonds for the construction of water works.

Lancaster, Pa.—The Special Water Com. of City Council is stated to have prepared an ordinance for the construction of a new force main and the erection of another standpipe, to improve the city's water supply. The people will be asked to approve a loan of $145,000 to do the work.

Jesup, Ia.—The citizens are stated to have voted Aug. 25 to construct water works, to cost about $5,000.

Joliet, Ill.—The following bids are reported received Aug. 25 for constructing reservoir: Jas. H. Roche, Chicago, $18,753; McEwen Bldg. & Mfg. Co., Chicago, $13,681; Wm. Tunny, No. Center St., $13,460.

Paulsboro, N. J.—Winfield S. Thompson is reported interested in a company which proposes constructing water works here, at a cost of about $16,000.

Westerville, O.—G. H. Mayhugh, Secy. Water Wks. Trus., writes that T. C. Brooks & Sons, of Jackson, Mich., have secured the contract for constructing water works, bids for which were opened Aug. 19; contract reported to amount to $23,700.

W. Alexandria, O.—Bids will be received by the Bd. of Water Wks. Trus. until Sept. 16 for constructing an extension to the water works system. Work to include, approximately 2,500 ft. of 4 to 8-in. pipe, 3,200 lbs. of special castings, 5 fire hydrants, with necessary valves, valve boxes, etc. L. M. Derby, Clk.

Oakland, Cal.—Mayor Barstow is stated to have signed the ordinance appropriating $40,000 for the reconstruction of 12th St. dam. City Engr. F. C. Turner is reported to have completed the plans for this improvement, and the contract will be let at once.

Anaheim, Cal.—The Fairview Water Co. has been incorporated, with a capital of $5,000. Directors: E. A. Sparkes, L. A. Evans, and others, of Anaheim. Principal place of business is Anaheim.

Whittier, Cal.—N. W. Stowell, of Los Angeles, is stated to have purchased from the East Whittier Land & Water Co. its pumping plant, 14 miles of irrigation ditch and 126 acres of water-bearing land. It is reported that the new owners will expend $40,000 in improvements, it being their intention to extend the ditch so as to cover the entire Lahabra Valley.

Havre de Grace, Md.—The Crystal Springs Water Co. is reported incorporated, with a capital of $60,000, to construct water works. Wm. H. Brown and Geo. R. Carver are among the incorporators.

Fultonville, N. Y.—J. M. Johnson is stated to have submitted a proposition to the Village Trus. to construct water works.

Wildwood, Pa.—A press report states that the Baltimore & Ohio R. R. Co. will construct a water and coaling station at Wildwood, to take the place of the Glenshaw and Bakerstown stations. J. M. Graham, Ch. Engr., Baltimore, Md.

Portland, Ore.—Local press reports state that about $75,000 will be expended for laying new water mains on the East Side.

Wagner, S. D.—W. G. McDonald, Town Clk., writes that the citizens have voted to issue $2,000 bonds for sinking an artesian well.

Oakcliff, Tex.—At a citizens' meeting Aug. 28 a committee is stated to have been appointed, with E. G. Senter as Chmn., to investigate the question of procuring a good water supply and a system of fire protection for Oakcliff.

Portsmouth, O.—Henry Scott, Jr., Secy. Water Works Trus., writes that no bids were received Sept. 2 for furnishing labor and material and installing an intake crib in the Ohio River. The Board will ask all parties to whom plans and specifications were sent to make bids; if no bids are then received they will in all probability construct crib and make necessary repairs themselves, under the supervision of the consulting engineers.

Sherman, Tex.—The citizens are stated to have voted on Aug. 29 to issue $35,000 water bonds and $15,000 sewerage bonds.

Freehold, N. J.—The Avon Water Co. and Well Co. are stated to have been consolidated and reincorporated as the Monmouth Water Co., with a capital of $1,000,000, and will furnish water for a number of towns in Monmouth County. Jas. Steen, Secy., Eatontown; Jas. Bray, Treas., Point Pleasant.

Richmond, Va.—The Common Council has passed an ordinance giving the Mayor authority to sign a contract with the Chesapeake & Ohio R. R. whereby the city obtains a right to run flumes and water raceways through certain property of the company in return for which the railroad is given a right to construct either a double or single track railway upon the bank and dam of the proposed settling basin. It is stated that the next move in the direction of clearer water for Richmond will be the consideration of a resolution providing ways and means for obtaining the $350,000 which will be required to construct the basin.

Bozeman, Mont.—It is stated that bids are wanted at once by the Bozeman Creek Reservoir Co. for a dam to cost $10,000. F. W. Bull, Secy.; C. M. Thorpe, Engr. in Charge.

Edmonton, Alberta, N. W. T.—It is stated that bids are wanted Sept. 17 for a compound duplex pumping engine of 600 gal. per minute, 2 centrifugal pumps of 600 gal. per minute, and two 20-H.-P. steam engines. Willis Chipman, Ch. Engr., 103 Bay St., Toronto, Ont.

Atlantic City, N. J.—Van Sant & Boegm, Atlantic City, have been awarded the contract for taking up old 20-in. submerged ball-joint pipe with saddles and piles under Beach Thoroughfare at $2.90 per lin. ft., and for laying new line at $7.90 per lin. ft. or $9.25 with 5-yr. guarantee. Kenneth Allen, Engr.

Kirkwood, Mo.—Bids are wanted Sept. 16 for furnishing material and constructing a water works distributing system. W. M. Daly, Mayor. Owen Ford, Consulting Engr., 710 Security Bldg., St. Louis, Mo.

Palo Alto, Cal.—The citizens are stated to have voted Aug. 30 to issue $28,000 bonds for extending the water works and $12,000 for the electric light plant.

Biloxi, Miss.—Engrs. Kirkpatrick & Johnson, write that the time for receiving bids for 7 miles of cast-iron mains has been extended from Sept. 9 to Sept. 16.

Saginaw, Mich.—J. A. Bacon, in his report to the Bd. of Pub. Wks., states that for supplying the west side with water, 16 wells would be needed, the cost of which would be $18,000.

Kansas City, Mo.—The following bids are reported opened Sept. 1 for a pump for Turkey Creek station: Holly Mfg. Co., Lockport, two types of 15,000,000-gal. pump, $148,000 and $163,000, 18 mo. time; Henry R. Worthington, New York, 10,000,000-gal. pump, $73,000, at once; Barr Pumping Co., Phila., 15,000,000-gal. pump, $115,500, 12 mo. time.

SEWERAGE AND SEWAGE DISPOSAL.

Vincennes, Ind.—Frank Joyce, Asst. City Engr., writes that bids will be received until Sept. 22 for 2,660 ft. of 24x30-in. pipe sewer.

Marshall, Mich.—Bids will be received by E. D. Dickinson, Co. Drain Comr., until Sept. 11 for cleaning out, deepening, widening and extending drain known as "Shultz & Davidson Drain."

Port Huron, Mich.—Bids will be received by R. D. O'Keefe, Supt. Pub. Wks., until Sept. 12 for constructing a main sewer in Beard and 20th Sts.

Eaton, Colo.—Bids are wanted Sept. 20 for constructing a sewer system. Wm. L. Petrikin, Chmn. Com.

Iola, Kan.—Bids are wanted Sept. 11 for constructing sewer outlet, septic basins and sewer mains and laterals in Dist. No. 1. J. H. Harris, City Engr.

Trenton, N. J.—Bids are wanted Sept. 9 for constructing sewers in portions of several streets. C. Edw. Murray, City Clk.

Norristown, Pa.—Bids are wanted Sept. 15 for constructing storm sewers, as advertised in The Engineering Record.

South McAlester, Ind. Ter.—See "Water."

Cincinnati, O.—J. B. Washburn is stated to have secured the contract for a sewer in Quebec and Jonte Aves., for $38,323.

Wakefield, Mass.—A press report states that at a special town meeting Aug. 25 $60,000 was appropriated for the Metropolitan Sewerage System, making a total thus far of $285,000, and the work is only about half finished.

Columbus, O.—The Dirs. of Pub. Wks. are stated to have recommended to Council the early construction of main trunk sewers on the West Side. The money for this improvement will be secured from the sale of $175,000 bonds authorized under the Longworth act. About $100,000 will be spent on the West Side and the balance in extending the sewer system on the South Side.

Jersey City, N. J.—Henry Byrne, 548 Montgomery St., is stated to have secured the contract for constructing sewers in Academy and Newkirk Sts., Baldwin Ave. and other streets in the hilltop section, for about $42,288.

Wyoming, O.—Riggs & Sherman, of Toledo, are reported to have been selected to prepare plans for a sewerage system.

Brooklyn, N. Y.—Ch. Engr. H. R. Asserson, of the Dept. of Sewers, states that bids will be advertised in about 20 days for building a 4-ring brick sewer mostly in tunnel, 6,200 ft. long and 13 ft. internal diameter, from 92nd St. and New York Bay to 11th Ave., including 425 ft. of extension into the bay on pile grillage foundation. In order to determine the character of the geological formations, level of ground water, etc., prospective bidders will be allowed to sink test wells or make boring at their own expense, as the several strata to be passed through are not to be guaranteed in any manner by the city. Estimated cost of this work, $665,000.

Eugene, Ore.—Mummey Bros. are stated to have secured the contract for a 16-in. sewer from the main sewer of 15th St. in the alley between Oak and Pearl Sts., for $6,200.

Antigo, Wis.—Harding, Nelson & Johnson, of Racine, are stated to have secured the contract for constructing a sewer system at Antigo, for $19,000.

Berkley, Va.—The following bids were opened Aug. 21 by the Improvement Bd., for 28,000 ft. pipe sewer, 4 to 15 in. in diam., including 40 manholes, 12 catch-basins and 22 flush tanks; trench averaging 7 ft. deep in earth: Wolford Evans Plumbing Co., Newport News, Va., $27,803; Southern Pavg. & Constn. Co., Chattanooga, Tenn., $27,712; A. L. Patterson & Co., Rome, Ga., $23,301; Guyla & Co., Chattanooga, Tenn., $22,561.

Pittsburg, Kan.—W. W. Cook & Son, Junction City, Kan., have been awarded contract for 16,617 ft. pipe sewer, 15 to 18 in. in diam., including 31 manholes and 1 flush tank, trench averaging 12 ft. deep in clay, gravel and rock; total, $22,700 in city; $3,300 outside city.

Portland, Me.—Bids are wanted Sept. 10 for constructing a portion of Alms House Valley sewer. Address Geo. N. Fernald, Comr. of Pub. Wks.

Allegheny, Pa.—Bids are wanted Sept. 9 for constructing lateral sewers in portions of several streets. D. L. Fulton, Dir. Dept. Pub. Wks.

Dallas, Tex.—The citizens are stated to have voted on Aug. 26 to issue bonds for new sewers.

Brooklyn, N. Y.—Bids will be received by J. Edw. Swanstrom, Boro. Pres., until Sept. 17, for furnishing material and constructing sewer crossings under Atlantic Ave. Improv., Subway, at Howard, Saranac, Rockaway and Hopkinson Aves., and Eastern Parkway Extension. Engr.'s estimate, 2,300 lin. ft. of 30-in. brick sewer, 294 ft. of 12 to 24-in. vitrified stoneware pipe sewer, 144 ft. of 18 and 24-in. cast-iron pipe sewer, 30 manholes, 22,000 ft. B. M. foundation planking, 430,000 ft. B. M. sheeting and bracing, etc. Bids will also be received at the same time for furnishing material and constructing sewers in 60th St. and in 19th Ave. Engr.'s estimate, brick sewer 15 ft. 162-in., 4,015 ft. 156-in., 660 ft. 144-in., 60 ft. 78-in., 50 ft. 36-in. and 100 ft. 30-in.; 350 ft. of 12 to 24-in. vitrified stoneware pipe sewer laid in concrete, 21 manholes, 16 receiving basins, 680,000 ft. of B. M. foundation planking, 2,300,000 ft. B. M. sheeting and bracing, etc.

Youngstown, O.—It is stated that bids are wanted Sept. 20 for constructing a sewer in a portion of South Ave. C. E. Cross, Clk.

Ft. Keogh, Mont.—See "Government Work."

Monticello, Ind.—It is stated that bids are wanted Sept. 12 for constructing sewer No. 14. W. J. Gridley, Town Clk.

Sherman, Tex.—See "Water."

Plainfield, N. J.—Jas. Maybury & Son, Passaic, N. J., on the basis of bids opened Sept. 2, has been awarded the contract for 25,855 ft. 8-in. pipe sewer in trench 7 to 14 ft. deep, excavated mostly in sand; total, $15,745. The work includes 29 manholes, 1,000 branches and 18 flush tanks.

Monticello, Ind.—Simons & Mikesell, Quincy, Ill., are reported to have received contract for Jefferson St. sewer at $13,554.

Mobile, Ala.—The following bids are reported received Aug. 28, by Bd. of Pub. Wks. for 21,659 ft. of 10 to 30-in. storm sewers, including 25,000 ft. 6-in. house connections, 1,500 ft. of 5-ft. brick sewer and 2,150 ft. 4x7-ft. covered canal: A. L. Patterson & Co., Macon, Ga., $86,499; Thos. Wagner, Mobile, Ala., $79,423; Jett Bros., Mobile, Ala., $86,938; Gilsonite Construction Co., St. Louis, Mo. (awarded contract), $78,258; T. W. Nicol & Co., Mobile, Ala., $115,752; Guild & Co., Chattanooga, Tenn., $105,001; Grasser Construction Co., New Orleans, La., $123,460.

Brooklyn, N. Y.—The following bids were opened Aug. 27 by J. Edw. Swanstrom for sewers in Ave. G. Flatbush and other streets:

Items.	Cunningham & Kearns.	John J. Creem.	John McNamee.
Brick sewer:			
90-in., 3,260 ft.	$27.00	$26.50	$20.00

BRIDGES.

Chillicothe, O.—Press reports state that the officials of the Norfolk & Western R. R. intend building a steel bridge, with triple girders, across Scioto River in this city. The contract for the masonry has been awarded. At Kinnick, it is stated that the company intends building a 290 ft. span bridge, with seven 48-ft. girders of trestle. It is also stated that at Ashville and Sciotoville, bridges are to be built in the near future. C. C. Wentworth, Bridge Engr., Roanoke, Va.

Pontiac, Mich.—It is stated that the city contemplates constructing a concrete bridge, 61 ft. wide and 30-ft. span. Wm. J. Fisher, City Engr.

Milwaukee, Wis.—Chas. J. Poetsch, City Engr., has been directed to prepare plans for a steel viaduct 1 mile long to be built at 27th St.

City Engr. Poetsch estimated the cost of constructing the Jones Island bridge at Washington St. at $150,000.

Richmond, Va.—Local press reports state that the Citizens' Rapid Transit Co. has had plans prepared for a viaduct to be built at Marshall St., at a probable cost of $125,000.

Pekin, Ill.—The Com. on Bridges will, according to local press reports, recommend to the City Council the building of a steel bridge in this city at a cost of $24,000.

Ottawa, Ont.—The building of a bridge across Rideau Canal at Concession St. is again being agitated.

Navarre, O.—The Canton-Akron R. R. Co. has petitioned the Co. Comrs. for permission to construct a bridge at Navarre.

Grand Rapids, Mich.—Plans and specifications for the piers and abutments for the Wealthy Ave. bridge are to be prepared at once, and the contract let as soon as plans are completed. It is stated that the bridge at Bridge St. will not be constructed until next spring.

Barbourville, Ky.—The Brackett Bridge Co., Cincinnati, O., is reported to have secured the contract to construct a bridge in Knox Co., across Cumberland River, for $11,800.

St. Charles, Ill.—E. H. Arnold is stated to have secured the contract to construct a bridge at Main St. for $12,000.

Springfield, Mass.—The War Dept. has issued an order directing the City of Springfield to either raise the 4th span of South-end bridge or place a 70-ft. draw in the bridge.

Picton, N. J.—The Lehigh Valley R. R. Co. has granted permission to the Plainfield & Elizabeth Trolley Co. to construct a bridge across the tracks at Picton.

Victoria, B. C.—Bids are wanted Oct. 13 for the Point Ellice Bridge, as advertised in The Engineering Record.

Yellowstone Park, Wyo.—See "Government Work."

Tarentum, Pa.—F. M. Ross writes that bids will be received until Sept. 15 for building a combined street railway and highway bridge for the Tarentum Traction Passenger Ry. Co. over the West Penn R. R. Probable cost, $50,000. Knoff & Milholland, Engrs.

Clayton, Mo.—Bids will be received until Sept. 15 by Wm. Elbring, Comr. of Roads & Bridges, for constructing 3 steel bridges in St. Louis Co.

Cedar Falls, Ia.—It is stated that the Chicago Great Western Ry. intends to build a steel girder bridge across Dry Run in the south part of the town. F. R. Coates, Ch. Engr., St. Paul, Minn.

Seattle, Wash.—The Bd. of Pub. Wks. is stated to have rejected bids for building the Latona bridge, the lowest bid being $5,000, which was considered by Engr. Thomson to be $1,000 too much.

South Bend, Ind.—Local press reports state that the Co. Comrs. will have plans and specifications prepared at once for a bridge to be built at Mishawaka over the St. Joseph River near the Barbee Creek culvert on 2d St.

Chicago, Ill.—The Drainage Bd. is reported to have authorized the expenditure of about $13,000 as "extra work" in building a temporary bridge at Harrison St. by the present contractor.

San Diego, Cal.—City Engr. d'Hemmecourt is reported to have prepared plans for 4 styles of bridges to span the San Diego River on the Poway Road, as follows: Pile bridge, to cost $7,942; wooden truss bridge, 50-ft. spans, to cost $9,621; combination wood and iron bridge, 162-ft. spans, to cost $22,823; combination bridge, 100-ft. spans, to cost $20,333; steel bridge, 140-ft. spans, to cost $31,823; steel bridge, 100-ft. spans, to cost $30,450.

Canisteo, N. Y.—Press reports state that the Town Bd. has issued $9,000 in bonds to be expended on bridges.

Joplin, Mo.—The Co. Court has authorized the Bridge Comr. to receive bids for a bridge across Turkey Creek on the Tuckahoe road.

Reading, Pa.—Press reports state that the bridge over the Schuylkill has been estimated to cost $30,000.

Angola, Ind.—The Goshen & Indiana Traction Co. is reported to be taking steps toward building bridges between Orlund and Lake James and across the Pigeon River at Ontario, La Grange Co. J. A. Van Osdol, Secy., Anderson, Ind.

Reading, Pa.—Bids will be received until Sept. 23 at the office of T. L. Eyre, Supt. of Pub. Grounds & Bldgs., Harrisburg, for rebuilding the substructure and superstructure of the bridge across Schuylkill River, in Ontelaunee Township, about 5½ miles north of Reading.

Santa Rosa, Cal.—The Bd. of Superv. is stated to have altered the plans for the bridge across Russian River at Markhams and awarded the contract to the San Francisco Bridge Co. The bridge will have two 200-ft. spans of steel and wood, and the cost will be, according to reports, about $21,000.

Berryville, Va.—The Bd. of Superv. has been requested by citizens of Clarke Co. to prepare plans for bridges over the Shenandoah River at Castleman and Berry's ferries. It is stated that $10,000 will be needed for the work.

Solon Springs, Wis.—The town of Nebagemain has been petitioned to construct a bridge across Lake St. Croix at this place.

West Chester, Pa.—Geo. T. James, Jos. Milus, J. O. Houck and others are reported interested in building a bridge over the south branch of French Creek, between the townships of East Nantmeal and Warwick.

White Haven, Pa.—Bids are wanted Sept. 23 for rebuilding the superstructure and substructure of the bridge across Lehigh River, at White Haven. Estimated cost, $38,000. T. L. Eyre, Supt. of Pub. Grounds & Bldgs., Harrisburg.

Chicago, Ill.—A. R. Porter, Clk. Trus. Sanitary Dist. of Chicago, writes that the opening of bids for constructing the superstructure and substructure of the 18th and Loomis St. bridges has been postponed until Nov. 5. Bids were to have been opened Sept. 3, as advertised in issue of The Engineering Record, July 19.

Doylestown, Pa.—Bids will be received by the Co. Comrs. until Sept. 15 for constructing a stone bridge in Nockamixon Township, at White's Mill. Bids will also be received by the Co. Comrs. until Sept. 20 for constructing a steel bridge across Poquessing Creek, between the city of Philadelphia and Bensalem Township. Elmer E. Funk, Clk.

Montesano, Wash.—It is stated that bids are wanted Sept. 15 for constructing a highway bridge over Porter Creek, consisting of a 64 ft. span, on pile abutments and 144 ft. of approaches. W. D. Campbell, Co. Clk.

Harrisburg, Pa.—Bids will be received until Sept. 23 at the office of T. L. Eyre, Supt of Pub. Grounds & Bldgs. for rebuilding the superstructure and substructure of the following bridges: 1 across Sugar Creek, at East Troy; 1 across Towanda Creek, Masontown; 1 across Wyalusing Creek, at Wyalusing; 1 across Lycoming Creek, near Fields Station, Lewis Township, 1 across Loyalsock Creek, Plunkett Township, Lycoming Co.; 1 across Lehigh River, Bowmanstown; 1 across Lackawanna River, Boro. of Old Forge, Lackawanna Co.; 1 across Tionesta Creek, 9 miles from Tionesta; 1 across Susquehanna River, at Tunkhannock; 1 across Tunkhannock Creek, at Dixon; 1 across Tuscarora Creek, Juniata Co.; 1 across West Branch of the Susquehanna River, near Curwensville; 1 across Red Bank Creek, at Brookville; 1 across Elk Creek, in Hillsgrove Township, Sullivan Co.; 1 across Lackawaxen Creek, 2 miles west of Honesdale, and 1 at Honeadale.

Wilkesbarre, Pa.—Bids will be received by the Co. Comrs. until Sept. 13 for constructing several small county bridges. Geo. R. McLean, Co Compt.

Terre Haute, Ind.—Bids will be received until Sept. 18 at a joint session of the Comrs. of Virgo and Sullivan Counties, at the office of Jas. Soules, Co. Aud. of Virgo Co., for constructing Allen bridge, 50-ft. span and 14-ft. roadway, and Dwyer bridge, 40-ft. span, 11-ft. roadway.

Washington, D. C.—Local press reports state that the construction of 2 landing bridges at the proving grounds at the Navy Yard are being considered. Probable total cost, $60,000.

Grand Rapids, Wis.—The Modern Steel Structural Co., of Waukesha, is reported to have secured the contract to construct a bridge in this city for $15,437.

Rockdale, Ia.—W. J. Harrahan, Ch. Engr. of the Illinois Central Co., is reported to have asked the Bd. of Superv. for permission to construct a viaduct at Rockdale.

Greenlane, Pa.—It is stated that plans and specifications are being prepared for a bridge to be built at Snyder's Mill, between Greenlane and Perkiomenville.

Philadelphia, Pa.—Bids will be received until Sept. 20 for bridge work as follows: bridge on line of Frankford Ave., between Philadelphia and Bucks Counties; work on west approach of bridge on Frankford Ave., in Philadelphia Co.; and abutment and piers of west approach to proposed Passyunk Ave. bridge over Schuylkill River. Wm. C. Haddock, Dir. Dept. Pub. Wks., Bureau of Surveys.

PAVING AND ROADMAKING.

Greenville, Miss.—Robt. Somerville, Asst. Chief Engr., Bd. Mississippi Levee Comrs., writes that Sessions & Cary, Greenville, were awarded contract for 800,000 cu. yds. levee work at 22 cts. per cu. yd.

Des Moines, Ia.—J. C. Likes is reported to have been awarded contract for about 11,097 sq. yds. brick paving on E. Lyon St., at $1.69 per sq. yd. O. P. Herrick bid $1.59 on condition that work was done in 1903.

Detroit, Mich.—Jas. Hanley is reported lowest bidder for resurfacing with sheet asphalt according to bids opened Aug. 25, as follows: Smith Ave., $2.10 per sq. yd., total, $18,220; Milwaukee Ave., $2.12 per sq. yd., total, $6,544; Horton Ave., $2.105 per sq. yd., total, $16,656.

Allegheny, Pa.—Bids are wanted Sept. 9 for grading, paving and curbing on portions of several streets. D. L. Fulton, Dir. Dept. Pub. Wks.

Youngstown, O.—Bids will be received by the City Comrs. until Sept. 13 (readvertisement) for paving a portion of Holmes St. C. E. Cross, City Clk.

Mays Landing, N. J.—The Special Road Com. of the Co. Bd. of Freeholders is stated to have decided to recommend to the Bd. the proposed route through Chelsea Heights as the site of the new turnpike. Co. Engr. Albertson estimated the new road will cost about $90,000. The foundation of the highway will be of gravel. The road later will probably be covered with macadam.

Dallas, Tex.—The citizens are stated to have voted Aug. 26 to issue $25,000 bonds for street improvements.

Peekskill, N. Y.—Bids will be received by the Bd. of Village Trus. until Sept. 16 for paving with brick on a 5-in. concrete foundation on portions of 3 streets. Albert E. Cruger, Clk.

New York, N. Y.—Bids will be received by the Comrs. of Parks, Wm. R. Wilcox, Chmn., until Sept. 11 for improving Crotona Parkway, from 175th to 182d Sts. Engr.'s estimate, 13,500 cu. yds. earth excavation, 7,500 cu. yds. rock excavation, 1,000 cu. yds. filling in place, 28,800 sq. yds. telford macadam pavement, 3,950 sq. yds. of asphalt walks, 14 receiving basins, etc.

Bids will be received until Sept. 11 by Jacob A. Cantor, Boro. Pres., for regulating and repaving with asphalt blocks on macadam foundation, or with a bituminous macadam pavement, 7th Ave. from 110th to 153d Sts. Engr.'s estimate, 100,400 sq. yds. of asphalt block or bituminous macadam pavement, 1,100 sq. yds. of old stone block pavement to be relaid in approaches, etc.; 17,500 lin. ft. of old curbstone redressed, rejointed and reset on concrete foundation; 5,500 lin. ft. of new curbstone furnished and set on concrete foundation, etc. Bids will also be received at the same time for regulating and repaving with asphalt on present pavement relaid as foundation on Henry St., between Rutgers and Grand Sts. Engr.'s estimate, 9,100 sq. yds. of asphalt pavement including binder course, 9,200 sq. yds. of old stone pavement to be relaid as foundation or in approaches, etc.; 4,400 lin. ft. of new curbstone furnished and set, etc.; also for similar work on portions of 63d and 102d Sts., requiring about 3,040 sq. yds. of asphalt pavement, including binder course, and 3,040 sq. yds. of old stone pavement to be relaid as foundation or in approaches, etc.

Trenton, N. J.—Bids are wanted Sept. 9 for paving with sheet asphalt on a concrete base on a portion of So. Broad St. C. Edw. Murray, City Clk.

Fremont, O.—Bids will be received by the Council's Improv. Com. until Sept. 29 for grading, draining and macadamizing a portion of State St. E. Schwartz, Chmn.

Moline, Ill.—Bids will be received by the Bd. of Local Improv. until Sept. 12 for grading, curbing and paving with asphalt on portions of 5th Ave. and 7th St., requiring in all about 7,412 sq. yds. of asphalt paving and 4,577 lin. ft. of curbing; estimated cost, $20,123. Bids will also be received at the same time for grading, curbing and paving with asphalt on 11th St., requiring 1,056 sq. yds. of paving and 704 lin. ft. of curbing; estimated cost, $3,040. Henry G. Paddock, Secy.

Kenosha, Wis.—Bids will be received by the Street Assessment Com. until Sept. 13 for furnishing material and grading, curbing and paving with vitrified brick on a crushed stone foundation, on N. Main and Main Sts. Chas. H. Pfennig, Chmn.

POWER PLANTS, GAS AND ELECTRICITY.

Battle Lake, Minn.—Bids will be received by the Village Council until Sept. 22 for $5,000 bonds, said bonds to be used to construct an electric light and water power plant. John J. Rudh, Pres.

Pagosa Springs, Colo.—Gilbert Wilkes & Co., 251 Coronado Bldg., Denver, is to construct an electric light plant in connection with the water works here. The water works are now being constructed.

Verndale, Minn.—H. Lyons, Village Recorder, writes that the citizens voted Aug. 18 to issue $7,000 bonds for an electric light plant.

Coeur d'Alene, Idaho.—See "Water."

Guthrie, Okla. Ter.—Fredk. G. Bonfils, of Denver, is stated to have petitioned the City Council for a franchise to establish an electric and gas plant and an electric railway, to cost in all about $150,000.

New Haven, Conn.—The Riter-Conley Mfg. Co., of Pittsburg, Pa., and C. W. Blakeslee & Sons, of New Haven, are reported to have secured the contract for the steel gas reservoir to be erected on East St. for the New Haven Gas Light Co.; total cost of work is about $200,000.

Council Bluffs, Ia.—It is stated that the Citizens Gas & Electric Co. will expend about $15,000 improving its gas plant.

Cincinnati, O.—Plans for a new distributing station and light plant to be erected on Charles St. and Central Ave. are stated to have been submitted to the Building Inspector by the Cincinnati Gas & Electric Co. It will cost $60,000 and will be of brick and steel.

Leadville, Colo.—A press report states that a new company, to be known as the Leadville District Ry. & Power Co., will construct an electric light plant here. T. W. Kloman, of New York, N. Y., is reported interested.

Hudson, O.—The Council is stated to have granted Goeppinger & Backman, of Youngstown, a franchise for an electric light plant.

Duluth, Minn.—City Engr. Patton is stated to have submitted to the Council his preliminary report of the cost of installing a municipal and commercial lighting plant. He estimates the cost, figuring that the city would use a maximum of 500 arc lights on the streets, at $150,000. The figures are based on an aerial system, except in the center of dense population, where the wires would be placed underground.

Parnassus, Pa.—The Parnassus Electric Light, Heat & Power Co. is reported incorporated, with a capital of $1,000.

Winnsboro, S. C.—W. B. Smith Whaley & Co., of Columbia, are stated to have been selected to prepare plans for an electric light plant.

Rome, Ga.—The City Council is stated to have passed a resolution requesting the City Attorney to prepare a bill for the Legislature to authorize the issue of $15,000 bonds for the construction of an electric light plant.

Flandreau, S. D.—It is stated that the Practical Gas Works, of North Chicago, Ill., will construct a gas plant here.

Harrisville, Mich.—The citizens are stated to have voted to issue $4,500 bonds for an electric light plant.

Miller, S. D.—Lewis Kellough is reported interested in the construction of an electric light plant.

Storm Lake, Ia.—City Clk. W. C. Edson writes that on Aug. 25 it was voted to grant franchises to A. W. Unger for a gas plant and to Storm Lake Electric Light & Power Co.

Lathrop, Mo.—The citizens are stated to have granted J. D. Guyton a franchise for an electric light plant.

Pana, Ill.—T. C. Reed, of Casey, Ill., is stated to have secured the contract for constructing an electric light plant for $16,000.

Carberry, Man.—It is stated that E. S. Harrison, of Winnipeg, proposes constructing an electric light plant and telephone system in Carberry.

Odell, Ill.—Foster & Thompson, of Pontiac, are stated to have made a proposition to the Village Trus. to furnish Odell with electric lights and also to pump the water.

Marion, O.—H. E. Bradner is stated to have petitioned for a franchise for a hot water and steam heating system.

Cleveland, O.—The Co. Comrs. are stated to have granted the East Ohio Gas Co. a perpetual franchise to lay gas pipes through the county.

Palo Alto, Cal.—See "Water."

Washington, Ia.—The Electrical Equipment Co., of Chicago, Ill., is stated to have secured the contract for constructing a municipal electric light plant, at $12,510.

Johnstown, Pa.—The City Council has granted franchises to the Consumers' Light, Heat & Power Co. and to the Citizens' Light, Heat & Power Co.

Williamsburg, Va.—A press report states that an electric plant will be erected at William and Mary College, to cost about $5,000.

Weiser, Idaho.—See "Water."

Depew, N. Y.—The Village Trus. are stated to have granted a franchise to the Depew & Lancaster Gas Co.

Lancaster, O.—It is stated that bids are wanted Sept. 18 for $40,000 bonds, the proceeds to be used to erect a natural gas pumping plant. M. T. Michling, City Clk.

Taylorville, Ill.—The Council is stated to have decided to construct an electric light plant, under the direction of Owen Ford, of St. Louis, Mo., at a cost of about $18,000.

ELECTRIC RAILWAYS.

St. Louis, Mo.—The Central Rapid Transit Co. is stated to have petitioned the Co. Comrs. at Clayton for a franchise to construct an electric railway on the Olive St. road between St. Louis and Creve Coeur Lake. John H. Blessing, Pres.

Salem, Ark.—The Salem & Eastern R. R. Co. has been incorporated, with a capital of $5,000, to construct an electric railway from Salem to a point on the Frisco R. R. Incorporators: R. A. Youngblood and H. F. Northcutt.

Toledo, O.—Jas. J. Robison, cashier of the Ohio Savings Bank & Trust Co., representing the Toledo, Angola & Western Ry. Co., is stated to have secured a franchise from the Co. Comrs.

Guthrie, Okla. Ter.—See "Power Plants, Gas and Electricity."

Santa Cruz, Cal.—Engr. D. M. Murphy is stated to have completed the survey for the Del Monte & Pacific Grove Electric Ry., and is now running a preliminary survey to Capitola from Santa Cruz.

Danville, Ill.—The Danville, Paxton & Wilmington Electric Ry. Co. is reported incorporated by J. W. Dale, of Danville, Chas. Bogardus and J. P. Middlecoff, of Paxton, and others.

Eddystone, Pa.—The Boro. Council is stated to have granted the Chester Traction Co. a right of way for a branch line from the Darby division over Eddystone Ave. to connect with the Southwestern cars. A. G. Jack, Supt., Chester.

Hamilton, O.—The Ohio & Indiana Ry. Co. is reported incorporated to construct a line from Hamilton to Richmond, Ind.

Aurelius, N. Y.—The Council is stated to have granted the Auburn City Ry. Co. a franchise to extend its line through Aurelius. D. A. Dyer, Jr., Supt., Auburn.

South Glens Falls, N. Y.—The Hudson Valley Ry. Co. is stated to have made a contract with Daniel H. Cowles to build the proposed South Glens Falls-Saratoga trolley line. The contract does not provide for the overhead work, which the company will do itself.

Volney, N. Y.—G. Adolphus Manz, of Syracuse, is stated to have petitioned the Highway Comrs. for a franchise to construct an electric railway from Volney to Fulton and Scriba.

Toledo, O.—The People's Rapid Transit Ry. Co., of Toledo, is reported interested in the construction of another interurban line to start at Toledo, running through Napoleon, Defiance, Paulding, Van Wert, Celina and Greenville. The road will connect at Greenville with the Dayton & Western.

York, Pa.—The York County Traction Co. is reported to have ordered surveys for two new routes, one extending from York to Wrightsville, the other from York to Hanover. J. F. Dusman, Mgr., York.

Wabash, Ind.—The City Council is stated to have granted a franchise to the Ft. Wayne & Southwestern Traction Co.

Philadelphia, Pa.—A permit is stated to have been granted by the Bd. of Highway Superv. to the Philadelphia Rapid Transit Co. to lay tracks for an extension of its lines in the southern section of the city

Herkimer, N. Y.—The Highway Comrs. are stated to have granted a franchise to the Utica & Mohawk Valley R. R. Co. to construct a line on the north side of the river between Little Falls and Herkimer. C. L. Allen, Gen. Mgr., Utica.

Canastota, N. Y.—The Village Trus. are stated to have granted a franchise to the New York & St. Louis Trolley Co. C. J. Parker, of Canastota, is reported interested.

Reading, Pa.—A press report states that plans are being prepared for an electric plant to be constructed by the Reading Ry. Co. at Kissinger's Dam, on the Schuylkill, in this city. Electricity will be generated by large turbine wheels.

Duquesne, Pa.—The Duquesne Traction Co. is reported incorporated, to construct a railway on the hill district in the residence section of the town and extend through a part of Mifflin Township to Lincoln Place. The promoters are Dan. G. Donovan and I. Lincoln Jones, of McKeesport, and John Crawford, of Duquesne.

North Yakima, Wash.—The Yakima Valley Central Ry. is reported incorporated, by J. F. McNaught, O. A. Fechter and others, to construct an electric railway from this city down the valley to Sunnyside and to connect other points with North Yakima.

Beaumont, Tex.—Harry K. Johnson, of Natchez, Miss., is about to petition for a franchise for a single track electric railway from Beaumont to Port Arthur, a distance of about 17 miles.

Woods Hole, Mass.—The Cape Cod St. Ry. Co. is reported to have been organized, with Walter O. Luscombe as Pres. and Geo. E. Dean, Secy. Work on the construction of the line will probably begin about Nov. 1.

St. Louis, Mo.—Two bills granting franchises for electric elevated street railways to run through the central, northern and southern portions of the city were introduced in City Council Aug. 29. One granting a franchise to the Park Elevated Ry. Co., the other to John R. Dwyer, 4936 Lindell Boule., and associates.

Springfield, Ill.—The Springfield & Central Illinois Ry. Co. has been incorporated, with a capital of $200,000, to construct a line from Springfield to Decatur; a southern branch from Springfield to Carlinville, and a western branch from Springfield to Jacksonville. Incorporators: St. John Boyle, Louisville, Ky.; and C. K. Minarty and David McKeown, Springfield.

Adrian, Mich.—Preliminary surveys are stated to have been completed by the Adrian, Jackson & Electric Ry. for a line between Adrian and Vandercook's Lake. The line will be about 37 miles in length.

Georgetown, Ill.—It is stated that the Terre Haute St. Ry. Co., of Terre Haute, Ind., is to build a line to Georgetown, Ill., to connect with the new interurban road from Danville. The distance from Terre Haute is 45 miles. The company is also stated to have secured a franchise to construct a line in Dana, Ill.

Richmond, Va.—See "Water."

Dallas, Tex.—The City Council has granted A. K. Bonta a franchise to construct an electric railway on N. Harwood St.

Rochester, N. Y.—The State R. R. Comrs. have granted the Rochester, Syracuse & Eastern R. R. Co. permission to construct its line. Clifford D. Beebe, Gen. Mgr., Syracuse, states that he length of proposed line will be about 91 miles, and the power plant will have a capacity of between 6,000 and 7,000 H.-P.

Elizabethtown, Ky.—S. Lambert, of White Mills, Ky., is reported interested in the construction of an electric railway from Elizabethtown to Millerstown.

Little Falls, N. Y.—The Highway Comrs. are stated to have granted a franchise to the Utica & Mohawk Valley R. R. Co. C. Loomis Allen, Gen. Mgr., Utica.

RAILROADS.

St. Louis, Mo.—M. W. Wambaugh, Ch. Engr. Missouri & Southeastern Const. Co., writes that the contract for grading, masonry and timber bridging on 32 miles of heavy work near St. Louis, has been awarded to McArthur Bros. Co., of Chicago, Ill.

Sligo, Mo.—The Sligo & Eastern Ry. Co. is reported incorporated, with a capital of $120,000, to construct a railroad from Sligo to Dillard.

Euclid, Pa.—A press report states that the Pittsburg, Bessemer & Lake Erie R. R. Co. has asked for bids for the construction of a coal road from the main line at Euclid to Pfaff's mines. The road will be about 18 miles long, and on it will be a 1,000-ft. tunnel. It will cost about $1,500,000. H. T. Porter, Ch. Engr., Pittsburg.

Ironton, Mo.—The Granite R. R. Co. has been incorporated, with a capital of $30,000, to construct a railroad 3 miles in length in Iron County. Incorporators: F. P. Ake, Ironton; A. J. Sheehan, Graniteville, and others.

Tuskegee, Ala.—It is stated that the Tuskegee R. R. Co. has been incorporated, with a capital of $75,000, to extend the short line connecting Chehaw and Tuskegee into the business district of Tuskegee. Incorporators: E. T. Varner, G. W. Campbell, and others, all of Tuskegee.

Washington, Pa.—A press report states that the Wabash R. R. Co. will construct a line through Washington. W. S. Lincoln, Ch. Engr., St. Louis, Mo.

Connellsville, Pa.—A charter has been granted to the Connellsville Central R. R. Co., with a capital of $120,000, to construct 12 miles of railroad in the new Klondike coke region of Southwestern Fayette County. Incorporators: Herbert Depuy and John H. Hillman, of Pittsburg, and others.

Co. will erect the following buildings at New Castle Junction, Pa.: A 22-stall round house; 35x50-ft. office building; 60x85-ft. machine shop; 25x60-ft. blacksmith shop; 20x60-ft. engine room; 35x60-ft. boiler room; 30x65-ft. storehouse, and 30x35½-ft. oil storage. The capacity of the power plant for electric lighting, heating and shop purposes will be 500 H.-P.

The Horseshoe Mining Co., Deadwood, S. Dak., has let contracts to the Allis-Chalmers Co. for machinery for a 500-ton cyanide mill. Contracts for tanks and other material will soon be let.

The National Pottery Co., Evansville, Ind., will erect a building 400 ft. long with an average width of 107 ft. and having 60,000 sq. ft. floor space. The power plant will consist of a 75-H.-P. engine and two 80-H.-P. water-tube boilers. A. M. Weil, Pres.

The James E. Thomas Co., Newark, O., will erect a 300x110-ft. foundry building and install a 250-H.-P. boiler, two 125-H.-P. engines and generators, five electric traveling cranes, motors for blowers, etc.

McLaren & Co., Chippewa Falls, Wis., have let a contract for building a 4-story, 44x160-ft. shoe factory to be run by water power.

The American Condensed Milk Co., Indianapolis, Ind., will erect a 2-story, 110x200-ft. building at Effingham, Ill. Four 100-H.-P. high-pressure boilers and an electric plant, including a 100-H.-P. engine, will be installed. A tin can plant will also be erected. J. V. Dittemore, Secy. & Mgr.

Frank Geyer, Hightstown, N. J., is interested in the erection of a 3-story, 250x50-ft. woolen mill. Arrangements for the power plant have been made, but the advisability of installing an additional 50-H.-P. boiler is being considered. Contracts for electric light plant, shafting, hangers, belting, pulleys, dyehouse outfit and interior telephone have not been let. Information concerning oil-burning apparatus for boilers is desired.

The Buffalo, N. Y., Weaving Co. is erecting a 2-story, 41x150-ft. addition to its plant. Electric power of 100 to 150 H.-P., furnished by the Niagara Falls Power Co., will probably be used.

H. C. Hubbell & Co., Somerset, Ky., are in the market for a second-hand high-speed engine to develop 125 H.-P. at 90 lbs. steam, two 100-Kw. monocyclic generators in good condition, fifty 1,200-c.-p. inclosed alternating-current arc lamps, 6 miles of No. 6 wire and 2 miles of No. 4 wire.

The Buffalo Foundry Co., Perry & Mississippi Sts., Buffalo, N. Y., has recently decided to increase its capital stock from \$10,000 to \$300,000 and will build a large jobbing plant, which will consist of a 320x145-ft. foundry of steel, equipped with two 30-ton and four 10-ton electric traveling cranes, six 5-ton and six 2-ton jib cranes, 102, 84 and 66-in. shell cupolas, 15-ton air furnace and air plant; a 3-story, 50x200-ft. pattern making and storage building, and a 30x320-ft. supply building. The plant will be so arranged that a 145x400-ft. open-hearth steel department and machine shops can be added when necessary. Electric power from Niagara Falls will be used.

The Lane & Bodley Co., Cincinnati, O., is planning a foundry for its Corliss engine business and jobbing. The foundry will be 120-ft. wide and of indefinite length, the land owned by the company admitting of its extension for about 1,000 ft.

The Lumbermen's Tool Co., Ltd., 422 Widdicomb Bldg., Grand Rapids, Mich., will erect a plant at South Boardman, Mich., and is in the market for boilers and engine of about 100 H.-P., lathe, planer, drill press, shears, etc. Geo. S. Burleson, Cedar Springs, Mich., manager.

The Marietta, O., Paint & Color Co. is building a 30x50-ft. working room and other additions to bring the floor space up to 2,000 sq. ft. A 20-H.-P. engine, with 3-inch line shafting, will be installed.

BUSINESS NOTES.

The Pittsburg Plate Glass Co. has let a contract to the Wm. B. Scaife & Sons Co., Pittsburg, for a 2,500-H.-P. We-Fu-Go water softening and purifying system to be erected at their Elwood, Ind., plant, which will treat well water containing large quantities of scale-forming and corroding substances, for use in the boiler plant. Other recent contracts include the following: Union Steel Co., Donora, Pa., 500,000 gals.; Penna. Salt Mfg. Co., Wyandotte, Mich., 150,000 gals.; The Ogemaw Co., North Bay City, Mich., 1,500 H.-P.; West Branch, Mich., 500 H.-P.; The Lancaster Mfg. Co., Clinton, Mass., 1,000,000 gals.; The Gibson Mfg. Co. Concord, N. C., 100,000 gals. J. Howard Ewald, 83 Laclede Bldg., St. Louis, has been appointed agent of the Scaife and We-Fu-Go systems for Southern Illinois, Missouri and Texas.

The Empire Iron & Steel Co., Niles, O., will begin operations Oct. 1, its product being iron and sheet steel and angles for light structural work. The output of iron and steel angles will be 100 tons daily. The galvanizing plant will be in operation about Jan. 1. The officers of the company are: Pres. & Treas., Wade A. Taylor; Vice-Pres. & Mgr., Chas. S. Thomas; Secy., J. F. O'Dea.

The United Steel Co., Canton, O., has placed an order for four 250-H.-P. water-tube boilers with the Pittsburg Gage & Supply Co., Pittsburg. Other recent contracts include power transmitting machinery for the Maryland Paper Co. and a rope transmission for the State Institution for Feeble Minded, Polk, Pa.

Thos. Potter, Sons & Co., Philadelphia, manufacturers of oil-cloth and linoleum, have adopted electric power distribution for the operation of printing machines, blowers used for drying oil-cloth, elevators and other general work throughout the plant. They have recently purchased from the Westinghouse Electric & Mfg. Co. six induction motors, to be operated from two-phase, 220-volt alternators.

THE ENGINEERING RECORD.

Volume XLVI., Number 11.

TABLE OF LEADING ARTICLES.

A New Departure in Consulting Engineering.... 241
Concrete-Steel Theory and Computations........ 241
The Bank of the State of New York. (Illustrated.) 242
Standard Specifications for Cast-Iron Pipe...... 245
The Cost of Dredging with Different Classes of Plant 247
Reconstruction of the Lake Winnibigoshish Dam. (Illustrated.) 250
Relation Between Macadam Roads and Electric Street Railways 252
An Investigation of a Garbage Crematory........ 253
The Convention of the New England Water Works Association 257

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

A New Departure in Consulting Engineering.

An incident of much significance is marked by the appearance of a report, printed elsewhere in this issue, made by a consulting engineer on the operation of a garbage crematory. This report is probably the first that was ever made in the United States by a sanitary engineer who has made a prolonged study of the subject in the United States and abroad, and bases his recommendations on a painstaking investigation of the condition and operation of such a plant. It has long been held by many observers of municipal conditions in this country that the problem of garbage disposal is one of the most unsatisfactory, in its present stage, of all which confront the city official. In many respects the condition resembles that which obtained 15 years ago in the mechanical filtration of water. At that time the competition between holders of various patents was so severe that comparatively little attention was paid by them to the scientific investigation of the processes they were advocating. Some of the results of this strife were to be seen in the expenditure of considerable sums for plants wholly unsuited to the situations for which they were built, and in the suspicion and occasional contempt with which conservative engineers regarded the rapid filtration of water and the use of a coagulant. It was the investigation of the Louisville Water Company into the merits of mechanical and other systems of filtration, conducted in an impartial manner and with scientific skill by Mr. George W. Fuller, which first demonstrated to the American engineering public the great value of the rapid system of filtration.

For the same reason it has long been the opinion of The Engineering Record that until a consulting engineer of high standing and thorough knowledge of the subject made an independent investigation and report on some garbage crematory in actual use, it would be almost hopeless to expect much advance in refuse destruction in this country. For this reason the report made by Mr. Hering to the authorities of Trenton is of exceptional value. He explains why it is that the actual destruction of the garbage by fire is only one part of a complicated system of working which must be reasonably perfect in all parts to be satisfactory to the public. The collection and disposal of garbage in large cities is a matter almost as important as the collection and disposal of sewage. It is more difficult in some respects, because these wastes from the houses and shops must be carried conspicuously through the streets and not removed out of sight through channels below the surface. From the receptacle where the garbage is collected to the ash pit where the clinkers are raked out of the crematory, there is a chain of operations which requires conscientious work on the part of laborers, skill on the part of managers and a high order of engineering ability on the part of designers of the plant. It is because Mr. Hering points out these features of the problem so well, and emphasizes his remarks by illustrations drawn from an existing crematory against which numerous complaints have been made, that his report must be considered a document of much importance.

It is to be hoped that this report is but the first of many which consulting engineers will be retained to make on this subject. The time has certainly gone by when the investigation of such a problem as is presented by the collection and disposal of the garbage of a city should be undertaken except with the assistance of an impartial, well-informed engineer. Hardly a month passes that The Engineering Record does not receive accounts of tours of investigation made by city officials to garbage plants in other places, for the purpose of ascertaining what sort of a furnace they should use in their own city. The information collected in this way may or may not be useful, but there is no question that if these tours are made in company with an independent expert the committee will return with numerous ideas of what not to do. There is hardly a garbage disposal system in the country today which cannot be improved, either in construction or in operation. Garbage disposal is the source of many unnecessary complaints and the cause of great waste of money. If other cities follow the example of Trenton these troubles will be greatly reduced.

Concrete-Steel Theory and Computations.

There will be found in The Engineering Record for August 23, an abstract in detail of an important and valuable paper on concrete-steel by Professor Brik. This paper is a comprehensive but concise statement of the concrete-steel problem as a branch of engineering construction as it now stands. Among other things Professor Brik gives results of some of the latest experimental investigations having for their purpose the determination of both the ultimate resistance and the moduli of elasticity of concrete in flexure, which depend not only on the age and quality of the material but also on the dimensions of the beam carrying the transverse load. Those who are to any extent familiar with the condition of our knowledge respecting the empirical quantities necessary for concrete-steel computations will easily realize the serious lack of data in these premises and the importance of securing them from suitably conducted experimental investigations.

There is little or no lack of experiments having for their purpose the determination of the modulus of elasticity for concrete in compression, nor unfortunately is there lack of wide diversity in results. It is evident enough that that modulus will increase with the age of the concrete for a considerable period of time, but the diversity remarked is found among results belonging to different specimens of concrete of the same age and of the same proportions of constituent elements. The tests of a Monier arch of seventy-five feet span by the Austrian Society of Engineers and Architects, as published in the Report for 1895, gives values of the compression modulus running from about 4,660,000 to nearly 5,180,000 pounds per square inch and with about one-fifth greater values for the tension modulus. By employing the horizontal and vertical deformations a kind of average modulus for the whole arch was found to be about 4,750,000 pounds per square inch, yet probably no civil engineer would consider it prudent to use in actual design as high a value as one approaching the lowest of those just given.

It is not uncommon to find a sharp distinction drawn between the values of the moduli of elasticity for concrete in tension and compression. Indeed, some, as Professor Hatt, take the compression modulus at even twice that for tension, while the Committee of the Austrian Society of Engineers and Architects found the tension modulus materially larger than the other in their tests of the seventy-five-foot Monier span, although it should be stated that the tension specimens had more age than those subjected to compression.

As a matter of fact experimental data are unfortunately far too meager at the present time to give any reliable relation between the two moduli, and there is at least some basis for the assumption that in concrete of considerable age they may be taken equal without much if any error. There is urgent need for careful experimental investigation with as large pieces of concrete as possible, both with and without steel reinforcement. In the meantime it seems scarcely necessary to complicate formulas for practical use with a difference between the two values certainly not yet established and about which there is serious doubt.

Another feature of this matter of which much is made is the variability of the modulus of elasticity of concrete with varying intensities of stress. A large amount of valuable data bearing on this point, and of most admirable character can be found in the "Report of Tests of Metals and Other Materials" at the Watertown Arsenal for 1899. Twelve-inch cubes of concrete of various proportions of cement, sand and broken stone or gravel and of age as much as six months were employed. A careful examination of those results will show that frequently permanent sets were observed at intensities of stress as low as two hundred pounds per square inch, while in other cases no such sets were observed under much higher stresses even up to one thousand pounds per square inch, or more. Indeed, the behavior of the concrete in at least one or two cases shows practically perfect elasticity up to nearly 4,000 pounds per square inch. A careful study of all those results must convince one that Portland cement concrete and mortars may properly be treated in computation as possessing an elastic limit in compression, with proportions of one, three and six or richer, of not much under 1,000 pounds per square inch, especially when proper balancing of the materials is practiced. This latter feature of concrete making, rapidly gaining in favor as it should, gives to the resulting material, among other advantages, enhanced elastic qualities. Undoubtedly when the stresses in concrete exceed 600 to 1,000 pounds per square inch the point is reached where the compression modulus may be expected to begin to decrease, but if the concrete is made as it should be at the present time, little or no error will be committed in assuming what may, with some privilege perhaps, be called the elastic limit at about 1,000 pounds per square inch. In many cases of rich mixtures such as one, two and four, it is not excessive to take that limit as high as 2,000 pounds per square inch. Inasmuch as these numerical results are based on figures actually derived from twelve-inch cubes of practically unbalanced constituents, it appears seriously doubtful, if not actually unjustifiable, to treat concrete as a material without much elastic behavior. This last observation has special force when applied to concrete-steel structures in which the comparatively great stiffness of the steel acts to a considerable extent as a kind of elastic aid to the concrete. Unquestionably in concrete-steel pieces the modulus of elasticity decreases rapidly as the intensity of stress approaches the ultimate resistance of concrete alone, and becomes probably but little more than zero in the composite piece when the intensity reaches its ultimate value, although no actual fracture of the concrete may take place. Just as marked an observation may, however, be applied to structural steel or any other ductile material. Yet no one would think of using anything but the formulas of the common theory of flexure for steel or wrought iron beams.

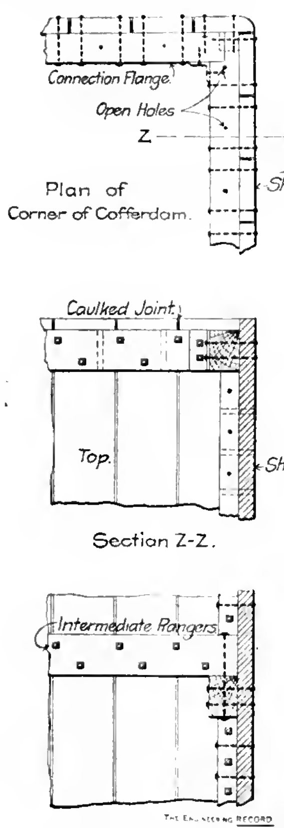
This is a very important feature of the concrete-steel matter. Too much effort has been made to represent what are supposed to be physical features of concrete so far removed from corresponding features of ductile materials as to make the formulas applicable to the latter inappropriate for the former. While it is probably unsafe to predict much as to what further investigations may disclose, it may with propriety be positively stated that little or nothing has yet been revealed which makes it necessary or advisable to assume a different law of variation of the bending stresses in concrete-steel beams or employ a different form of formula from those given by the familiar common theory of flexure.

The values of working stresses for the concrete in concrete-steel beams given by Professor Brik are certainly reasonable and safe and practically the same may be said of his moduli of elasticity. It is probable that in no case should the modulus be taken higher than 3,000,000 pounds per square inch, nor need it often be taken lower than 2,000,000 pounds per square inch, although there are special cases where 1,500,000 pounds would seem to be justifiable.

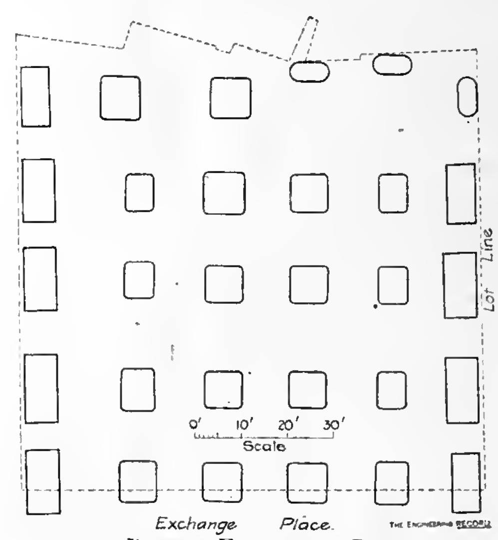
The Monroe Suit for Defective Fire Protection was fully explained in The Engineering Record of June 2, 1900, but the final judgment which the Louisiana Supreme Court has just rendered is an entire surprise to those familiar with its former decision. The case was a suit by a manufacturing company against a private water company for damages to its plant caused by defective fire protection. The first trial resulted in establishing the water company's responsibility if a defective supply could be proved. The second decision, 32 S. Rep. 376, is that the main reason for the fire department's poor work was the presence of the sprinkler system in the plant, which drew so much water from the mains that the two hydrants ran short. This releases the water company from liability. As this view is a novelty, the court's words are quoted: "The witnesses testifying who seem most familiar with the scientific rules governing the subject-matter with which they are dealing attribute any failure of the fire department of Monroe to have done more effective work than it might have done on the occasion of the fire on the plaintiff's property, not to any fault on the part of the defendant company, but to the existence of the sprinkler system upon the plaintiff's property, and to the fact of there being a continuous simultaneous discharge of water during the fire from all of its openings, through the connection of the system with the public mains, in close proximity to the public hydrants from which the defendant was operating."

The Bank of the State of New York.

The Bank of the State of New York occupies a site approximately 100 feet square on Exchange Place near Broad Street, New York City. It is a steel-cage building corresponding in general type to others of the same class which have been described from time to time in The Engineering Record, but varies somewhat from them in the character of the steel sub-structure, the wind bracing and column details. It will have a height of twenty-five stories or about 340 feet above the curb, and will have a basement and cellar below that level, the floor of the latter being about 21 feet below the curb and about 5 feet below the ground-water level. The superstructure will be supported on 27 main lines of rectangular steel columns in two-story sections, seated on 27 concrete piers carried down to solid rock by the pneumatic caisson process. Except under the side wall columns the caissons and piers are concentric with the columns. Under the side walls the columns are located as close as possible to the lot lines which brings them eccentric with their respective piers. They are arranged in five rows parallel with the street front and in six rows perpendicular to the first and parallel with the lot lines. This produces spaces of from about 18¼ to 23½ feet on centers between the piers.



DETAILS OF COFFERDAM.



PLAN OF FOUNDATION PIERS.

The main piers are all rectangular in cross-section and vary in size according to their total loads, which are calculated to produce maximum pressures of 30,000 pounds per square foot on the concrete. The wall piers are about 7 feet wide and 14 feet long and most of the interior piers are 8 feet square, but there are variations of a foot or two both ways from these dimensions which are over all and include the thickness of the cofferdams in which the piers were built. The exterior wall caissons have square corners, the interior ones have their corners rounded to a radius of 3 inches except three small ones supporting two-story columns under the light court, which are 4½ feet wide and 6½ feet long with semi-circular ends.

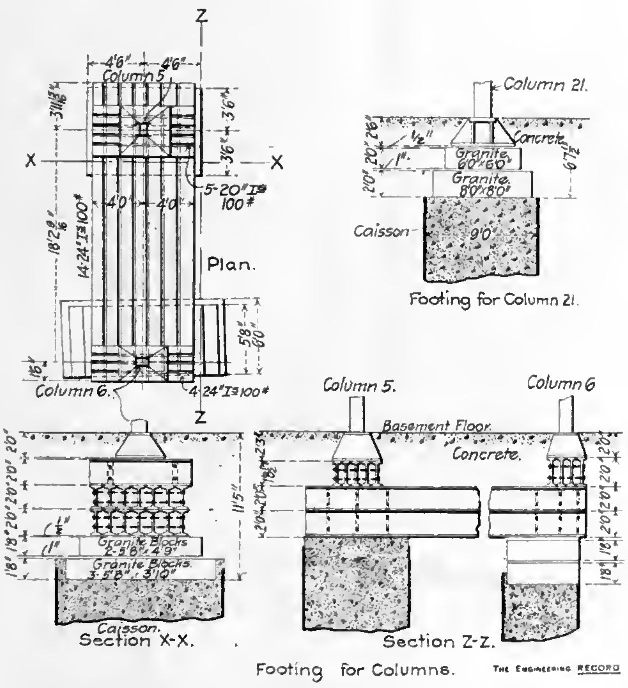
The site was previously occupied by a building under which there was no cellar and when it was removed the excavation was only carried down at first to a depth of about 6 feet below the curb. Sheet piling was driven across the street front and ten lines of horizontal 12x12-inch struts at curb level were set perpendicular to the tops of the piles and carried across the lot to bearing with 5-ton horizontal jack screws against vertical distributing pieces on the face of the wall of the adjacent building. About as many similar braces at right angles to these and in the same plane were carried across the lot and set against the side walls of the adjacent buildings on Exchange Place, thus forming a system of rectangular panels arranged so that the caissons were located inside the panels and cleared the braces. Caisson 26 is not in line with the others in the same transverse row, and the braces there could not be carried through straight, so the intersecting section of the brace was omitted and the end of the corresponding brace in the next panel took bearing against inclined braces diverging both sides of the caisson to the wall.

The sides of the panels were from 8 to 20 feet long and where the braces intersected at their corners one of them was continuous and the other one was cut to clear with butt joints on the sides of the continuous brace. The ends of the cut brace rested on a short-4-inch plank, which extended across the under side of the continuous brace and was supported on top of a vertical 12x12-inch post on the center lines of the struts. The foot of the post had a double wedge bearing on a short timber sill. Most of the braces were continuous from post to post, but sometimes splices occurred between posts and were made with butt joints and plank fish plates bolted on the vertical sides of the timber. A heavy deck of thick planks was laid on top of the braces at about street level and served as platform for unloading and storage and supported offices, dressing rooms for the caisson men, and a traveling derrick with which the caissons and materials were handled. Under the platform the air compressors, receiver, boilers, pumps and small shops were located and pipes were run to the caissons.

The derrick had a framed timber platform about 40 feet square with its sills braced by diagonal horizontal struts having beveled ends abutting against and bolted to them and having the joints made with plank scabs. At each corner of the platform the sills were of double thickness and formed seats for derrick masts 35 feet high. Each mast had a stiff leg reaching from its top to the opposite end of the platform sill in each adjacent face. The four sets of stiff legs thus made X-bracing in each vertical face of the traveler. There were no horizontal struts connecting the tops of the mast.

The feet of the stiff legs were beveled to horizontal and vertical surfaces, the former bearing on the sill and the latter against the end of a thick plank spiked to it. A 5x½-inch steel tie-plate was also bolted to each side of the foot of the stiff leg and to the sides of the sill. Each mast had a 50-foot boom with a capacity of about 10 tons. The traveler was operated by three double drum Lidgerwood hoisting engines and was moved on solid wooden rollers, set in either direction under the sills.

The caissons were made entirely of wood with vertical sheathing of 3-inch pine plank, 10 to 12 inches wide, planed outside and bolted to 6x8-inch horizontal inside rangers about 5 ft. apart with two ⅝-inch carriage bolts having outside heads which were not countersunk in the sheathing. The sets of rangers were separated by 3x3-inch vertical corner pieces, and the longitudinal rangers were lapped across the upper sides of the transverse ones. The caissons were 10 and 12 feet high over all with 8x8-inch inside horizontal timbers mitered together to form the cutting edge flush with the bottoms of the staves. The caisson roof was a deck of two solid courses of 8x8-inch timbers crossed. The caisson walls were carried up in the same vertical planes by the sides of the cofferdams which were made in one or two vertical sections from 10 to 18 feet high, according to the depth of the piers.



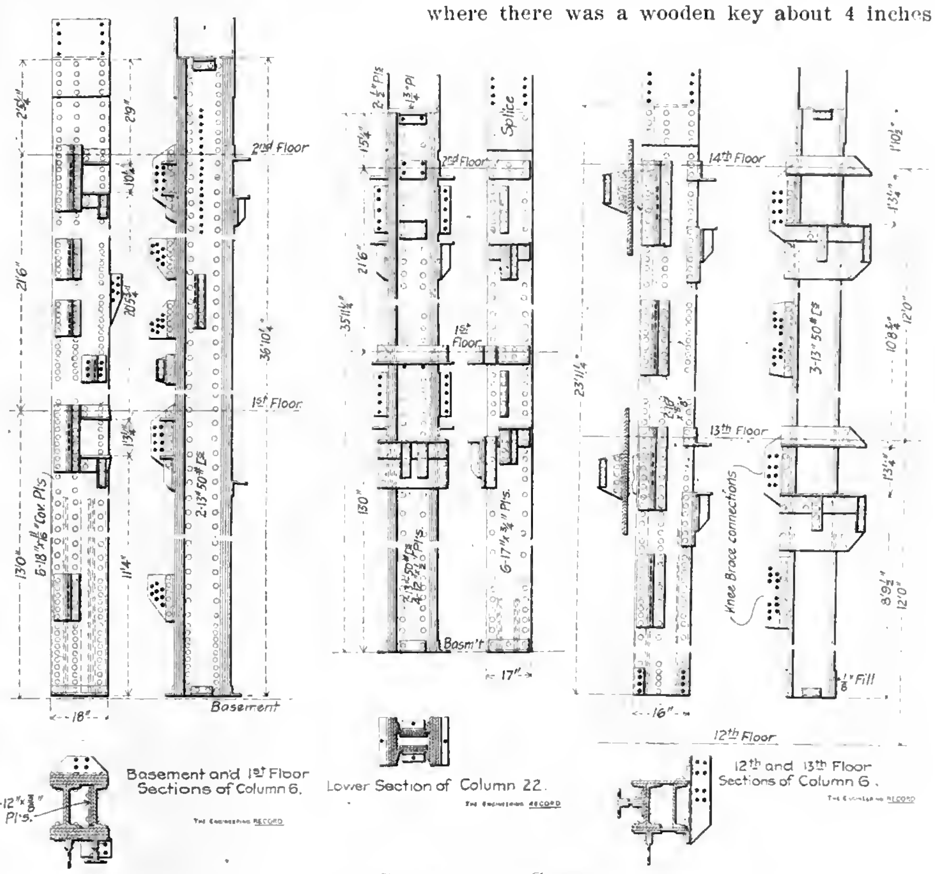
DETAILS OF COLUMN FOOTINGS.

blockaded by the buckets. The shafts were detached from the caissons before the latter were concreted. A maximum pressure of about 15 pounds was furnished by the two McKiernan air compressors, and pressure was on as many as three caissons at once. The caissons were sunk through earth, quicksand and clay with a little gravel to a stratum of hard pan about 4 feet thick, which was about 39 feet below the bench mark on the curb on the east side of the lot, and sloped to a depth of 46 feet on the west side.

The caissons were sunk with from 50 tons of pig iron for the smallest to 300 tons for the largest and descended at a maximum speed of 2 feet an hour, or 40 feet in 24 hours; one being sunk, concreted and the lock removed in 36 hours after air pressure was applied. They were sunk about 18 inches into the hard pan and stopped there while the excavation was carried down to the surface of the rock, which was carefully cleaned before concreting. The excavation was made a foot or two wider below the cutting edge than above it. The thirty caissons were sunk in about 40 working days

Battery Place Building foundations described in The Engineering Record of June 21. The locks were considered very satisfactory on account of their simplicity and the ease and rapidity with which they were operated. They were made high enough to allow the lower doors to drop in them above the top of the shaft and had separate doors for men and buckets. The bucket doors were fully counterbalanced and had single leaves pivoted on horizontal axes.

The caissons and cofferdam sections were built by the contractors at their yards in Long Island City and shipped whole to the site where they were delivered, generally at night, on large trucks drawn by two or three teams each. The largest caisson weighed about 10 tons, and was set in place by two booms of the traveling derrick. The wall caissons were sunk within about 6 inches of the lot line and were provided with greased vertical guide planks spiked to the walls of the adjacent buildings. The interior caissons were located exactly by intersecting transit lines and were sunk inside braced horizontal timber guide frames with a clearance of 6 inches, except in the centers of the sides where there was a wooden key about 4 inches



DETAILS OF COLUMNS AND CONNECTIONS.

The cofferdams were built like the caissons except that the bottoms were made like the tops and they had no roofs. The transverse and longitudinal rangers in the top and bottom sets were halved over each other at the ends so that both were in the same plane and formed inside flanges, about 2 inches clear of the ends of the sheathing boards. The joints were strengthened by vertical connection angles, as shown in the detail sketch, and the sections were connected by vertical bolts through the flange rangers. The sheathing planks were spaced with ¼-inch cracks between them which were calked with oakum and the ends were cut exactly square and even so as to match as perfectly as possible and were bolted together with hemp gaskets.

The caissons were sunk with 30x54-inch steel air shafts with inside guides between the bucket space and the ladder space and special air locks, patented by Mr. D. E. Moran, were arranged to serve for both men and materials without the possibility of the men ever being

and would have been sunk more quickly if operations had not been delayed waiting for the shoring and underpinning of the adjacent buildings. The caisson work was done by three 8-hour shifts of about 12 men each and the total number of men employed on the caisson and pier work was about 250.

The quantities involved were about 3,000 yards of excavation in the caissons, 4,000 yards of excavation outside the caissons, and 2,000 yards of concrete in the piers. Concrete was hand mixed on the platform at street level and was deposited in the caissons under pressure with cylindrical ½-yard buckets discharging through bottom flaps which were released when the descent of the bucket was arrested. The spoil was hoisted out of the caisson in ½-yard cylindrical steel buckets and dumped on the main working platform whence it was shoveled into wagons and removed at frequent intervals of the day and night. The buckets, shafts and air-locks used on this work were the same as those used by the same contractors for the

wide and 12 inches long with beveled ends, which took bearing on a well greased sheathing board.

The caissons were sunk to about 2 feet below water line, by open excavation before the air pressure was required, the excavation being made from within so that the sides of the caisson should prevent the necessity of sheeting which would have been required for an open pit excavation. The caissons were sunk with an accuracy of about 1 inch laterally. The three small caissons under the light court which supported short columns, differed from the other caissons in having rounded ends and horizontal 3x3-inch steel angle frames 4 feet apart to which the vertical sheathing planks were secured. The angles were in single pieces spliced with 3x½-inch cover plates. The caisson roof was a ½-inch steel plate stiffened with 3x3-inch angles and the cutting edge was reinforced by a 3x3-inch angle, horizontal flange down.

All of the piers are capped with two or three

2-foot courses of cut granite, the lower courses on the interior piers being about 2 feet wider and longer than the top courses. For the square piers each course is a single stone, the lower one about 1 foot narrower and shorter than the top of the pier after the latter is stripped of its cofferdam sheathing. In the long wall piers there are several stones in each course, each as long as the width of the course. These courses are all of the same width and are eccentric with the pier, the outer ends being flush with the outside face of the piers. The stones are set with ½-inch joints of cement mortar under the beds and under the cast-iron pedestals for the interior columns. The long wall piers and the interior piers adjacent to them support nine cantilever girders which carry the wall-columns at their extremities, about 3 feet outside the centers of the piers.

These girders are made up of double tiers of 24-inch 100-pound I-beams, with their flanges riveted together as indicated in the elevation, and the pairs of beams connected by tie-rods and separators. There are from five to eight pairs of beams in each girder and they are from about 20 to 29 feet long. Single-tier grillages of four or five transverse beams are set on both ends of the cantilever girders to receive the column bases and distribute their loads uniformly over all the separate elements of the girder. They are from 12 to 20 inches deep and are connected with separators and bolts. All girder and grillage beams are thoroughly painted two coats, covered with hot asphalt and are enclosed in a solid mass of concrete rammed between their webs and extending 2 inches beyond the sides and ends of the beams and up to the cellar floor to wholly enclose the cast-iron column pedestals.

The columns are made in two-story lengths, all in the same tier being spliced at the same level, 15¼ inches above the floor line, with two side plates and a horizontal diaphragm plate, which are field-riveted to the lower and shop-riveted to the upper ends of the columns. They have closed rectangular sections made up of plates and channels with a maximum cross sectional area of 176 square inches for a total load of 2,295,000 pounds. Column number 6 is one of the heaviest and has a special section made up of six cover plates and three channels, two of the latter riveted together back to back, and the other one with its web reinforced by two thick plates. In the upper tiers of this column the size and weight of the channels are maintained, but the sectional area of the column is reduced by diminishing the number, thickness and width of the cover plates and by omitting the channel web reinforcement plates.

This is a corner column and has vertical web plates projecting from two adjacent outer sides to receive the field-riveted connections of the wind bracing struts. It also has offset connections to support the wall girders clear of the two outer faces of the column. These are designed so that the same support receives the two girders meeting at one point in a horizontal plane. A vertical plate parallel with the channel web is shop-riveted to a pair of vertical angles, which have their other flanges shop-riveted to the edges of the cover plates, as shown in the cross-section. This plate has a 6x6-inch angle riveted to its upper edge with the horizontal flange bearing on the milled upper ends of reinforcement and distribution angles. The support being made eccentric to the column affords bearing for one wall girder parallel to the bracket angle and projects far enough past the edge of the column to receive the other girder, at right angles to the first one on the cantilever end. Corresponding

transverse angles without web plates receive the top flanges of the wall girders. On the opposite side of the column the girder connection is made to the vertical face of a bracket which has an I-shaped horizontal cross-section and is composed of four short 4x3-inch vertical angles and a web plate riveted through the webs of the double channels. In the basement story of the column the wind-brace connection on one side is a long bracket which is shop-riveted to the strut and has 18 field-bolts through both of the channel webs.

Wall column 22 has a load of 1,637,000 pounds in the basement story where its cross section is 130 square inches, made up of six cover plates, and two channels with their webs reinforced with two plates each. The wall girders are clear of the outer edges of the channel flanges and cover plates and those of adjacent panels abut on the center line of the column and are riveted on the same supporting angle bracket which is connected to the column by a vertical plate riveted to the edges of the cover plates as described for the corner column, but in this case, symmetrically. The other three faces of the columns have on their center lines connections for the floorbeams in three directions. These are simple angle brackets with reinforced horizontal flanges to support the lower flanges of the beams and corresponding angles without reinforcement to receive the upper flanges. The floor girders have in addition vertical connection angles shop-riveted to the column and field-riveted to one side of the girder web.

The intermediate wall columns in the street-front are similar to column 6, but have their channel webs at right angles to those in Column 6 and have the eccentric bracket plate riveted directly across the cover plates instead of at right angles to them. The floorbeam connections are in the center lines of the column faces and have simple bracket angles to receive the top and bottom flanges. The interior columns are all made with two channels and four cover plates in the lower stories, and have all beams and girders connected on the center lines of all four faces. The girders have reinforced horizontal bracket angles under the lower flanges and vertical angles for web connections; the floorbeams have no reinforcement for the lower flange bracket angles and have no web connections. Both beams and girders have top flange connection bracket angles field-riveted to both beams and columns.

In the typical floors there are parallel with the street two lines of main girders, composed of single 20-inch I-beams connecting the columns of the interior rows. They carry web connected 12-inch I-beam floorbeams 5½ feet apart perpendicular to the street line and proportioned for a total floor load of 160 pounds per square foot including the weight of the terra cotta flat arch panels. The wall girders are 12 and 15-inch I-beams bracketed out about 1 foot clear of the floor girders with riveted diaphragm plates about 5 feet apart and supported at the ends on the columns as shown in the details of columns 6 and 22. The floor girders between wall columns are I-beams 12 or 15 inches deep, according to span except where they serve as wind struts also and are either 24-inch I-beams, pairs of 15-inch channels or plate girders.

On the street front the wall girders are made extra deep up to and including the 10th floor, to act as wind struts, as indicated in the diagram of the lower part of the columns 1, 2, 3, 4, 5 and 6. Similar bracing is introduced in the lower 10 stories of one end of the second and third rows of interior columns parallel to columns 1-6, as indicated in the diagram of interior sway bracing, but the system is carried only through two of the five panels in the cross section of the building in each case. In both of the exterior walls which are perpendicular to the street front the bracing is carried up to and including the 15th floor as indicated for one of them in the diagram of the lower parts of columns 1, 7, 13, 19 and 25. In the opposite side wall all panels in the 15 lower stories are fully braced similarly to those in the first five stories between columns 1 and 25. In the last mentioned wall the horizontal struts are all pairs of 15-inch channels back to back. These are heavier in the middle than in the side panels and heavier below the 10th floor than above it. The diagonal braces are pairs of 8-inch channels down to and including the third floor, the remainder are pairs of 9-inch channels. The materials of the wind bracing in the other four planes are noted on the diagrams, and the details correspond to those shown in portions of the side and front walls. The wall girders which act as horizontal wind struts have at each end a pair of vertical flange angles field-riveted to opposite sides of their webs. One of these angles is shop-riveted to the side of the column a little beyond the center line, the other is shipped loose and is located so that the holes in one flange match the open holes through the channel flange and cover plate of the column and so can be field-riveted. When this connection is made to the channel web instead of the cover plate of the column neither row of rivets can be field driven and one angle is shop-riveted and the other is connected by bolts which pass through the column and have nuts bearing on the outside of the opposite channel. The wind bracing is proportioned for an assumed wind pressure of 30 pounds on the faces of the building above 100 feet from the ground.

Messrs. Clinton & Russell were the architects of the building, and Col. J. H. Wells of their staff was the structural engineer. Messrs. Purdy & Henderson were the consulting engineers for the structural steel work. The George A. Fuller Company was the general contractor, and the Foundation & Contracting Company were the sub-contractors for the caisson work. The structural steel has an estimated weight of about 3,000 tons exclusive of about 300 tons in the foundation girders and grillages, and is made by the Carnegie Steel Company.

Measures for the Prevention of Water Waste are being seriously considered by the Metropolitan Water and Sewerage Board of Boston. The daily consumption during 1901 was 117 gallons per inhabitant, and the last report of the board states that an increase in the next few years corresponding to that which has occurred since the beginning of the operations of the Board, will compel resort to be had in a very few years to additional sources of supply, some ten or twelve years earlier than had been estimated by the State Board of Health in 1895. Although it was found that the cost of determining the amount of water furnished to each city and town in the Metropolitan District would be considerable, the Board concluded that such cost would be justified if the different cities and towns could thus be given a pecuniary motive for enforcing proper regulations against waste. The Metropolitan Water Act provided that the annual assessment upon the cities and towns other than the city of Boston should be levied one-third in proportion to their respective valuations and the remaining two-thirds in proportion to their respective populations. The Board proposes to change this, so that the assessment shall be based one-third in proportion to the valuations and two-thirds in proportion to the quantities of water respectively used.

Standard Specifications for Cast-Iron Pipe.

At the meeting of the New England Water-Works Association held this week in Boston, the most important action was the adoption by a unanimous vote of the final report of the Committee on Standard Specifications for Cast-Iron Pipe. This Committee presented a preliminary report some months ago. Its discussion by engineers, water-works superintendents and foundrymen enabled the Committee to prepare its final draft with the advantage to be derived from a full understanding of the opinions of all interested. The original specifications presented in 1901 have been modified in many minor particulars as well as in the most striking feature. This was the proposition to give all pipe of the same nominal size a uniform outside diameter. The representatives of the pipe foundries convinced the Committee that the saving in the patterns for the outside of the pipe, were such a requirement adopted, would be a small matter compared with the vastly increased expense of fittings for casting the inside of the bell where the inside diameter varies with each class. There was beside a danger that the pipes would be of poor quality if too great differences in the thickness of the pipe were made by increasing the thickness of the clay on the core.

In the revised specifications, printed below, there are two patterns of outside diameter for all sizes from 4 to 16 inches, with one class of special castings; three patterns for all sizes of pipe from 18 to 60 inches, with two classes of specials from 18 to 24 inches, and three classes of specials for the largest sizes. Different classes for each pattern are obtained by making the outside diameter equal to the nominal diameter plus twice the thickness of the heaviest class of that pattern, the pipe of the heaviest class having the inside diameter equal to the nominal diameter and a uniform thickness from end to end. The lighter classes are obtained by reducing the thickness of the shell on the inside, except on the extreme ends, where it is to be the same as in the heaviest class and tapered to meet the thinner portion of the body of the pipe through a length not exceeding 6 inches.

To use one pattern of specials with two patterns of pipe, the joint room for the larger is made a little thinner than the standard joint of the pipes and a little thicker for the smaller pattern. No joint room, however, is less than 0.35 inch or more than 0.6 inch. Owing to the time occupied in the consideration of specifications of pipe, the Committee was unable to submit at the meeting complete tables for the specials. In general design, however, they are similar to those used by the Metropolitan Water Works.

It is rare that a water-works association reaches results of such wide value as those attending the adoption of these specifications. Cast-iron pipe is used so extensively that the great variation in the minor details of its form are a reproach to the business sagacity of the engineering profession. It is only by standardizing such supplies, admirably adapted for standardization, that the best quality of pipe and specials can be obtained at a minimum of cost and time. It is to be hoped that these specifications will receive the wide adoption that followed the recommendations of the American Society of Civil Engineers in the matter of rail sections. Finally it should be emphasized that Messrs. Coffin, Brackett and Forbes, who have given so much of their time to the Committee's work, deserve the warm thanks of all who have the good interest of water-works affairs at heart. The labor attending the preparation of such a report can only be appreciated by those who have carried on similar work.

Sec. 1. The pipes shall be made with hub and spigot joints, and shall accurately conform to the dimensions given in Tables 1 and 2. They shall be straight and shall be true circles in section, with their inner and outer surfaces concentric, and shall be of the specified dimensions in outside diameter. They shall be at least 12 feet in length, exclusive of socket. For pipes of each size from 4 to 16 inches in diameter there shall be two standards, and for each larger size three standards of outside diameter. The inside diameter of each class shall be increased from the nominal size in the manner hereinafter specified, so as to obtain the standard thickness and weight. For pipes from 4 to 16 inches in diameter one class of special castings shall be furnished with all classes of pipes. For pipes from 18 to 24 inches in diameter, Class D special castings shall be furnished with pipes of Classes A, B, C and D, and Class F special castings with pipes of Classes E and F. For pipes 30 inches in diameter and larger, Class B special castings shall be used with pipes of Classes A and B, Class D special castings with pipes of Classes C and D, and Class F special castings with pipes of Classes E and F.

All pipes having the same outside diameter shall have the same inside diameter at both ends. The inside diameter of the lighter pipes of each standard outside diameter shall be gradually increased for a distance of 6 inches from each end of the pipe, so as to obtain the required standard thickness and weight for each size and class of pipe.

Sec. 2. Especial care shall be taken to have the sockets of the required size. The sockets and spigots will be tested by circular gages, and no pipe will be received which is defective in joint-room from any cause. The diameters of the sockets and the outside diameters of the spigot ends of the pipes shall not vary from the standard dimensions by more than 0.06 inch for pipes 16 inches or less in diameter; 0.08 inch for 18, 20 and 24-inch pipes; 0.10 inch for 30, 36 and 42-inch pipes, and 0.12 inch for 48, 54 and 60-inch pipes.

Sec. 3. For pipes whose standard thickness is less than 1 inch, the thickness of metal in the body of the pipe shall not be more than 0.08 inch less than the standard thickness, and for pipes whose standard thickness is 1 inch or more, the variation shall not exceed 0.10 inch, except that for spaces not exceeding 8 inches in length in any direction, variations from the standard thickness of 0.02 of an inch in excess of the allowances above given shall be permitted.

Sec. 4. Defective spigot ends on pipes 12 inches or more in diameter may be cut off in a lathe, and a half-round wrought-iron band shrunk into a groove cut in the end of the pipe. Not more than 12 per cent. of the total number of accepted pipes of each size shall be cut and banded, and no pipe shall be banded which is less than 11 feet in length, exclusive of the socket. In case the length of a pipe differs from 12 feet the standard weight of the pipe given in Table No. 2 shall be modified in accordance therewith.

Sec. 5. All special castings shall be made in accordance with the cuts and dimensions given in the tables forming a part of these specifications. The diameters of the sockets and the external diameters of the spigot ends of the special castings shall not vary from the standard dimensions by more than 0.08 inch for castings 16 inches or less in diameter; 0.10 inch for 18, 20 and 24-inch pipes; 0.13 inch for 30, 36 and 42-inch pipes, and 0.16 inch for 48, 54 and 60-inch pipes.

The flanges on all manhole castings and manhole covers shall be faced true and smooth, and drilled to receive bolts of the sizes given in the tables. The contractor shall furnish and deliver all bolts for bolting on the manhole covers, the bolts to be of sizes shown on plans, and made of the best quality of mild steel, with hexagonal heads and nuts and sound, well-fitting threads.

Sec. 6. Every pipe and special casting shall have distinctly cast upon it the initials of the maker's name. When cast especially to order, each pipe and special casting shall also have cast upon it figures showing the year in which it was cast and a number signifying the order in point of time in which it was cast, the figures denoting the year being above and the number below; thus,

1901 1901 1901
.1 .2 .3

etc., also any initials, not exceeding four, which may be required by the purchaser. The letters and figures shall be cast on the outside and shall be not less than 2 inches in length and ⅛ inch in relief for pipes 8 inches in diameter and larger. For smaller sizes of pipes the letters may be 1 inch in length. The weight and the class letter shall be conspicuously painted in white on the inside of each pipe and special casting after the coating has become hard.

Sec. 7. No pipe shall be accepted the weight of which shall be less than the standard weight by more than 5 per cent. for pipes 16 inches or less in diameter, and 4 per cent. for pipes more than 16 inches in diameter; and no excess above the standard weight of more than the given percentages for the several sizes shall be paid for. The total weight to be paid for shall not exceed for each size and class of pipe received the sum of the standard weights of the same number of pieces of the given size and class by more than 2 per cent.

No special casting shall be accepted the weight of which shall be less than the standard weight by more than 10 per cent. for pipes 12 inches or less in diameter and 8 per cent. for larger sizes; and no excess above the standard weight of more than the above percentages for the several sizes will be paid for.

Sec. 8. All pipes and special castings shall be made of cast iron of good quality, and of such character as shall make the metal of the castings strong, tough, and of even grain, and soft enough to satisfactorily admit of drilling and cutting. The metal shall be made without any admixture of cinder iron or other inferior metal, and shall be remelted in a cupola or air furnace.

Sec. 9. Specimen bars of the metal used, each being 26 inches long by 2 inches wide and 1 inch thick, shall be made without charge as often as the engineer may direct, and in default of definite instructions the contractor shall make and test at least one bar from each heat or run of metal. The bars, when placed flatwise upon supports 24 inches apart and loaded in the center, shall for pipes 12 inches or less in diameter support a load of 1,900 pounds and show a deflection of not less than 0.30 inch before breaking, and for pipes of sizes larger than 12 inches shall support a load of 2,000 pounds and show a deflection of not less than 0.32 inch. The contractor shall have the right to make and break three bars from each heat or run of metal, and the test shall be based upon the average results of the three bars. Should the dimensions of the bars differ from those above given, a proper allowance therefor shall be made in the results of the tests.

Sec. 10. The straight pipes shall be cast in dry sand molds in a vertical position. Pipes 16 inches or less in diameter shall be cast with the hub end up or down, as specified in the proposal. Pipes 18 inches or more in diameter shall be cast with the hub end down.

The pipe shall not be stripped or taken from the pit while showing color of heat, but shall be left in the flasks for a sufficient length of time to prevent unequal contraction by subsequent exposure.

Sec. 11. The pipes and special castings shall be smooth, free from scales, lumps, blisters, sand holes, and defects of every nature which, in the opinion of the engineer, unfit them for the use for which they are intended. No plugging or filling will be allowed.

Sec. 12. All pipes and special castings shall be thoroughly cleaned and subjected to a careful hammer inspection. No casting shall be coated unless entirely clean and free from rust, and approved in these respects by the engineer immediately before being dipped.

Sec. 13. Every pipe and special casting shall be coated inside and out with coal-tar pitch varnish. The varnish shall be made from coal tar. To this material sufficient oil shall be added to make a smooth coating, tough and tenacious when cold, and not brittle, nor with any tendency to scale off.

Each casting shall be heated to a temperature of 300° Fahrenheit immediately before it is dipped, and shall possess not less than this temperature at the time it is put in the vat. The ovens in which the pipes are heated shall be so arranged that all portions of the pipe shall be heated to an even temperature. Each casting shall remain in the bath at least five minutes.

The varnish shall be heated to a temperature of 300° Fahrenheit (or less, if the engineer shall so order), and shall be maintained at this temperature during the time the casting is immersed.

Fresh pitch and oil shall be added when necessary to keep the mixture at the proper consistency, and the vat shall be emptied of its contents and refilled with fresh pitch when deemed necessary by the engineer. After being coated, the pipes shall be carefully drained of the surplus varnish. Any pipe or special casting that is to be recoated shall first be thoroughly scraped and cleaned.

Sec. 14. When the coating has become hard, the straight pipes shall be subjected to a proof by hydrostatic pressure, and, if required by the engineer, they shall also be subjected to a hammer test under this pressure.

The pressure to which the different sizes and classes of pipes shall be subjected are as follows:

	20-inch diameter and larger. Pounds per sq. in.	Less than 20-inch diameter. Pounds per sq. in.
Class A pipe.........	150	300
Class B pipe.........	200	300
Class C pipe.........	250	300
Class D pipe.........	300	300
Class E pipe.........	350	350
Class F pipe.........	350	350

SEC. 15. The pipes and special castings shall be weighed for payment under the supervision of the engineer, after the application of the coal-tar pitch varnish. If desired by the engineer, the pipes and special castings shall be weighed after their delivery, and the weights so ascertained shall be used in the final settlement, provided such weighing is done by a legalized weighmaster. Bids shall be submitted and a final settlement made upon the basis of a ton of 2,000 pounds.

SEC. 16. The contractor shall provide all tools, testing machines, materials, and men necessary for the required testing, inspection, and weighing at the foundry of the pipes and special castings; and, should the purchaser have no inspector at the works, the contractor shall, if required by the engineer, furnish a sworn statement that all of the tests have been made as specified, this statement to contain the results of the transverse tests upon the test bars.

SEC. 17. The engineer shall be at liberty at all times to inspect the material at the foundry, and the molding, casting, and coating of the pipes and special castings. The forms, sizes, uniformity, and conditions of all pipes and other castings herein referred to shall be subject to his inspection and approval, and he may reject, without proving, any pipe or other casting which is not in conformity with the specifications or drawings furnished.

SEC. 18. The inspector at the foundry shall report daily to the foundry office all pipes and special castings rejected, with the causes for rejection.

SEC. 19. All the pipes and other castings must be delivered in all respects sound and conformable to these specifications. The inspection shall not relieve the contractor of any of his obligations in this respect, and any defective pipe or other casting which may have passed the engineer at the works or elsewhere shall be at all times liable to rejection when discovered, until the final completion and adjustment of the contract, provided, however, that the contractor shall not be held liable for pipes or special castings found to be cracked after they have been accepted at the agreed point of delivery. Care shall be taken in handling the pipes not to injure the coating, and no pipes or other material of any kind shall be placed in the pipes during transportion or at any time after they receive the coating.

SEC. 20. Wherever the word "engineer" is used herein, it shall be understood to refer to the engineer or inspector acting for the purchaser, and to his properly authorized agents, limited by the particular duties intrusted to him.

A Septic Disposal System for the sewage of the county court building at Clayton, Mo., has recently been built in an adjoining public park by the Cameron Septic Tank Company, of Chicago. It has a capacity of 10,000 to 15,000 gallons per day and cost $2,750.

Disk Anchors for temporarily holding brush jetties have been designed by Mr. John O. Holman. They are mushroom shaped and 10, 16 and 20 inches in diameter. They are dished about one-fourth of their diameter and weigh 15, 26 and 50 pounds respectively. There is a large hole at the center and two smaller holes near by, the latter for securing the mooring cable. A hollow pipe with a conical nozzle is thrust into the large hole and the anchor and pipe sunk like a jet pile by forcing a stream of water down the pipe. When it is desired to take up the anchor, the end of the pipe is loosely attached to the cable so as to make the latter act as a guide and run down to the bottom; the jet of water is then turned on and in a short time the anchor is jetted free.

The Unusual Rainfall Conditions in eastern Massachusetts in the early part of 1901 are discussed in the report for that year of the Metropolitan Water and Sewerage Board. There was an unusually low rainfall and flow of the streams from the first of January to March 10. The average yield for the month of February on the Sudbury watershed was 300,000 gallons per day per square mile, while the next lowest record for that month in a period of 27 years was 541,000 gallons, and an average is 1,889,000 gallons. Immediately following this drought there was a remarkably large rainfall in March, April and May, nearly one-half the rainfall of an average year.

The Cost of Dredging with Different Classes of Plant.

Somewhat condensed from a paper read before the International Navigation Congress at Düsseldorf by Mr. John Bogart, M. Am. Soc. C. E.

The excavations for a large canal have been in progress under the direction of the writer during the years 1897, 1898, 1899, 1900, and 1901. In this period there have been moved 5,868,000 cubic yards. Of this material 1,436,000 cubic yards were excavated under water by dredgers of several different types, and 4,432,000 cubic yards were excavated above ground by steam shovels and certain special forms of graders and excavators and conveyors, this latter amount including 88,700 cubic yards of rock requiring blasting.

The canal is in St. Lawrence County, New York, and connects the St. Lawrence River with the Grasse River. Its length is 16,200 feet. It carries water from the St. Lawrence River above the Long Sault Rapids to the Grasse River, the water of which is at this point about 44 feet below that of the St. Lawrence. Here there has been built a power-house for the development of water-power and electricity. [The works have been fully illustrated in The Engineering Record of January 6, February 10 and November 3, 1900.] The design for the complete works includes a lock to transfer vessels from the canal to the Grasse River, and through that river to the St. Lawrence below the Rapids. The lift of this lock will vary with the elevation of the water in the two rivers—never exceeding 45 feet.

The alignment of the canal is very direct. It has but three curves, each of 5,730 feet radius. There are two deep excavations, each about 3,000 feet long, in which the natural surface has a maximum elevation of about 72 feet above water-surface in the canal. Throughout the remainder of its length the natural surface averages from 12 to 14 feet above water-surface. The whole canal is in excavation.

The St. Lawrence River, at the entrance to the canal, fluctuates in height about 2½ feet as a maximum. The fluctuations in the Grasse River are generally 4½ feet, the river being near its low stage during the greater part of the year. Occasionally the river has attained a height of 14 feet above low water for a few hours. This occurs only under certain conditions of ice, in winter, which set the water back.

The area of the water section of the canal when finally completed will be 5,870 square feet. The dimensions below water surface will be 187½ feet wide at bottom, 265.3 feet wide at water surface, 25.93 feet depth of water. The total excavation requisite to secure this water section will amount to 7,760,000 cubic yards.

After some progress had been made, it was decided to excavate at first a canal with a water section of 2,574 square feet, the reduction being made so as to permit the development of a large amount of power sooner than could be done if the whole excavation were completed before transmission of water through the canal. The canal with this reduced section has been completed. The present dimensions below water surface are: 155.8 feet wide at bottom; 199.3 feet wide at water surface; 14.5 feet depth of water.

The material excavated was largely alluvial deposit. A soft gray clay, with some sand, some gravel, some boulders, and with loam at the surface, was found everywhere, except at the two high ridges. At these the material was an indurated clay with gravel and large boulders. This indurated material was very difficult to excavate. Power and dynamite were used freely in all excavations made above water. Very powerful steam shovels could not work advantageously until the indurated material was blasted; the conditions of the locality, difficulty in obtaining suitable dredgers, and the unexpected failure of the two very large vacuum dredgers hereafter described, led to the excavation by steam shovels and other methods of dry removal for about three-quarters of the total amount moved, and only about one-quarter by dredging under water.

The dredgers used have been of the following types:

Centrifugal Pump Dredgers.—The excavation made by a rotary cutter; the excavated material forced to its place of deposit through long steel pipes. In one of these dredgers the pipe was 12 inches in diameter, in another it was 18 inches in diameter.

Dipper Dredgers.—The excavation made in the usual way by the scoop dipper with movable back; deposited in scows, and these towed by tugs to the place of deposit in water.

Vacuum Pump Dredgers—The excavation made by an orange-peel bucket, deposited in a hopper and transmitted by use of vacuum chamber through long steel pipes to place of deposit. This pipe was for these dredgers 18 inches in diameter.

The centrifugal pump dredger with suction and discharge pipes of 1 foot diameter was built on the ground where some excavation had been made, water was pumped to this excavation after the dredger was built so as to float it, and a sufficient supply of water was continued by pumping to allow the dredger to work without interruption.

The hull is southern pine, 65 feet long; 30 feet wide; 6 feet deep. The longitudinal timbers on bottom are 8x12 inches and 3 feet center to center. The timbers on each side of the center are double 16x12 inches. The side uprights are 6x8 inches and 3 feet center to center. The whole is covered by plank 3 inches thick. At the front of the hull is an A frame of timber 12x12 inches, reinforced by two steel 1¾ inch rods to each timber. The top of this frame is 45 feet high above the deck. It is anchored by two other timbers 12x12 inches, running from its top back to each side of the hull 24 feet from the front, and also by two 2 inch rods from its top to each side of the deck at the middle of the hull. Six feet above the deck is a cross-piece on the A frame, the center of which supports the foot of a timber boom or frame, the other end of which is supported by a wire cable from the top of the A frame. At the end of the boom are three sheaves, each carrying wire cable; two of these swing the dredger from side to side, the other raises and lowers the timber frame which supports the suction pipe, the cutting instrument, and the shaft operating this cutter. At the stern of the hull are two anchoring spuds of timber, 9x16 inches and 40 feet long. These are raised or lowered by cables running through sheaves on a square timber frame, and by means of these spuds the dredger is held in position and is moved forward or backward by raising one spud, swinging the hull, dropping that spud, raising the other, and swinging in the other direction.

The movable frame is 45 feet long, made of two timbers, each 12x12 inches, with space between them for the suction pipe, 12 inches in diameter. A shaft of steel 4 inches in diameter is above the suction pipe. The frame and its appurtenances is raised, lowered, and held in position by the cable from the A-frame passing through the sheave at end of boom and running to the engine. The suction-pipe and the cutter-shaft are jointed so as to allow free vertical movement of their supporting frame. The cutter is composed of blades which radiate from the end of the shaft and are curved backward and connected at their outer ends by a ring of metal, thus forming a skeleton basket-shaped frame, 3½ feet in diameter at base and 2 feet 10 inches deep. The shaft passes through the center of this cage and the blades are forged together and attached to the end of the revolving shaft.

The number of blades varies with the character of the material excavated, adhesive material and clay requiring greater space between the blades than free friable earth or sand. In the soft clay excavated by this machine a space of about 2½ inches between the blades was found advisable.

The end of the suction pipe is fixed at the rear or base of this cutter. When the shaft and cutter revolve, the blades loosen and cut into the material against which the cutter is held. This disintegrated material passes between the blades into the interior of the basket and thence directly into the suction pipe with a volume of water ranging with the character of material excavated. This pipe goes directly to the centrifugal pump. This pump is connected to a separate compound condensing engine of 125 horse-power. It is capable of operating against a head of 60 feet. It delivers the water and excavated material directly into the pipe which passes out from the stern of the dredger. This pipe is of wrought iron, spiral-riveted. Its lengths are connected by flanges bolted together, and at convenient intervals there are placed sections of heavy rubber pipe 6 feet in length, thus permitting all requisite changes of alignment. The length of the discharge pipe actually used for this work was generally 1,200 feet. The pump forced the water and material through this and greater lengths of pipe without difficulty. The lift above the surface of the water in which the dredger floated averaged 30 feet.

The Lidgerwood engine, which does all the work except actuating the pump, is in the forward part of the boat and has a cylinder 6¼x10 inches, link motion, with six drums. One drum raises and lowers the cutter and suction pipe; two drums swing the boat from side to side, and two raise and lower the anchoring spuds. The same engine turns the shaft of the cutter. The boiler is of 125 horse-power and supplies steam at a pressure of 125 lbs. Every movement of the machinery is controlled by one man, operating levers placed in a house on the upper forward deck of the dredger.

As the cutter revolves, the frame carrying it and the outer end of the suction pipe is slowly moved sideways, the whole boat swinging upon one of the anchored spuds as a pivot, until the edge of the required excavation is reached. The frame is then lowered enough to cut another slice of material, and then moved in the other direction. This operation is repeated until the proper depth is attained. Then the dredger is moved backward for another cutting.

The water with the excavated material is delivered at the outer end of the discharge pipe. The amount of material carried with the water varied from 7 to 30 per cent. The usual running average of excavated material was about 25 per cent. The semi-fluid mass was so directed that it spread over a considerable area of land, depositing the solids gradually, the water running to one of the rivers or at certain points back into the canal. When sufficient area was provided so that there was time for precipitation, the water became quite clear. When it ran to the river within a short time it carried with it about 2¼ per cent. of suspended material. This dredger was not able to excavate the indurated material above described. It did excavate successfully the soft clay and loam and sand, separately or as they occurred in combination. It worked continuously throughout each season, except when ice prevented. Rain and bad weather did not interfere with it. It was run 22 hours during each 24 hours, except on Sundays. It was served by two sets of men, each working 11 hours. It excavated and delivered during three seasons 459,800 cubic yards. The cutting was made to a maximum depth of 22 feet below the surface of water in which the dredger floated, and the material was raised an average of 30 feet above that water and deposited an average of 1,200 feet from the dredger. This dredger requires for its operation one captain, one engineman, one oiler, one fireman, one foreman of deck hands, and three men. The compensation of the force at the average rates paid during the progress of this work amounted for each shift of 11 hours to $17.95.

For each day of 22 hours	$35.90
Oil, waste, etc., for 22 hours	5.00
Coal, 9 tons at $3, for 22 hours	27.00
Total each 22 hours	$67.90

This amount includes the labor required in placing and taking care of the discharge pipe as well as in operating the dredger. The pay of the deck hands, the lowest-priced labor employed on this dredger, was $1.65 for the 11 hours, or 15 cents per hour. The above cost of $67.90 thus equals 41.18 days' pay of this class of labor. These laborers were selected as partially skilled men, the pay of common unskilled labor being 12½ cents per hour, or $1.375 per day of 11 hours. The price of coal is more than it would be in many parts of the United States.

The cost of this dredger was $40,000. Interest at 4 per cent. is $1,600 per annum. The life of the dredger would not exceed about ten years—that is to say, it would not require an expenditure equal to the original cost of the dredger to keep it in constantly good condition, and to have it in that condition at the end of ten years. There must therefore be charged against the work done $4,000 per annum for repairs and renewals, and $1,600 per annum for interest.

In the locality of this canal, and generally in the northern parts of the United States, dredging can only be done during about eight months of the year. The annual cost for repairs, renewals, and interest must in this particular case be distributed over the actual working days, say $26.80 per working day. The dredger must be cared for during the winter season, at a cost which, distributed over the actual working days, may be charged at $1 per working day.

The total cost per actual working day of 22 hours is thus:

Labor and supervision	$35.90
Coal at $3 per ton	27.00
Supplies	5.00
Interest, repairs and renewals	26.80
Care during winter	1.00
Total	$95.70

As stated above, this dredger excavated during three seasons 459,800 cubic yards. Very careful observations were made of actual working days occupied in the excavation of 218,250 cubic yards. This amount was excavated and discharged in 194 working days, thus giving for this large volume an average of 1,125 cubic yards per day of 22 hours.

The average cost was thus, with allowance for repairs, renewals, care in winter, coal, supplies, and labor, 8,507 cents per cubic yard.

It will be observed that if the cost of labor, coal, and supplies alone was taken into consideration, the resulting average cost would be 6.035 cents per cubic yard. This compares with statements of cost of dredging which have been made with reference to other works. The cost of capital invested and of repairs and renewals is certainly an actual element of cost of work done.

The centrifugal pump dredger with suction and discharge pipe of 18 inches diameter was substantially of the same construction as the one with 12-inch suction and discharge pipe already described quite fully. All parts were correspondingly larger. The hull of this dredger was that of one of the vacuum dredgers, hereinafter referred to, which was incapable of economically working in this material. The hull is 103 feet long, 34 feet wide, and 10 feet deep. The vacuum machinery and the excavating bucket and all attachments were removed. A centrifugal pump, 18-inch suction and discharge, and an engine, drums, cutter, cutter shaft, suction pipe and other machinery were put in.

The mode of operating this dredger is exactly the same as the 12-inch one already described. It excavated similar material. It worked through two seasons except when ice prevented. It was run 22 hours each day, except Sundays, and was managed by two sets of men, each working 11 hours. It excavated and delivered during two seasons 290,780 cubic yards. The cutting was made to a depth of 22 feet below the surface of the water in which the dredger floated, and the material was raised an average of 30 feet above that water, and deposited an average of 1,200 feet from the dredger.

This dredger requires for its operation one captain, one engineman, one oiler, one fireman, one spud-tender, one foreman of deck hands, and three men. The compensation of this force at the average rates paid during the progress of the work amounted for each shift of 11 hours to $20.95.

Or for each day of 22 hours	$41.90
Oil, waste, etc., for 22 hours	8.00
Coal, 18 tons at $3, for 22 hours	54.00
Total each 22 hours	$103.90

This included placing and taking care of the discharge pipe.

The cost of a new dredger similar to this one would be $60,000. Interest at 4 per cent. is $2,400 per annum. Repairs and renewals, as explained for the similar dredger, would be for this dredger $6,000 per annum. These distributed over actual working days would be $40.19 per working day. The care during winter distributed over the actual working days cost $1 per day.

The total cost per actual working day of 22 hours is thus:

Labor and supervision	$41.90
Coal at $3 per ton	54.00
Supplies	8.00
Interest, repairs and renewals	40.19
Care during winter	1.00
Total	$145.09

Careful observations show that this dredger excavated and discharged 246,983 cubic yards in 160 working days, thus giving an average of 1,543.6 cubic yards per day of 22 hours. The average cost was thus, with allowance for repairs, renewals, care in winter, coal, supplies, and labor, 9,399 cents per cubic yard.

The excavation made by dipper dredgers and delivered into scows at side of dredgers amounts to 525,306 cubic yards. One of these dredgers has a dipper with a capacity of 2½ cubic yards. The dipper has three steel teeth, about 6x5 inches. The hull is 85 feet long, 28 feet wide and 10 feet deep. There are three anchoring and supporting spuds, each 20 inches square. The dipper arm is 28 feet long, of wood sheathed with steel. The material was delivered into scows, each having a dropping pocket with a capacity of 140 cubic yards. A tugboat took these scows in turn into the St. Lawrence

River, dropping the excavated material in a bay near the mouth of the canal. The distance to which the scows were towed averaged about 5,500 feet.

The dipper dredger worked ten hours per day. The tug and scows could not be operated at night. This dredger excavated to a depth of 20 feet below water surface.

The cost of operating this dredger, including the crew of dredger, tug and scows, coal, supplies, etc., was for each day of ten hours $30.56.

The cost of dredger, tug, and two scows is $43,000. Interest at 4 per cent. is $1,720 per annum. One-tenth cost for repairs and renewals is $4,300 per annum. These distributed over actual working days would be $28.80 per working day. Care during winter months, distributed over working days, $1 per day. The total cost per actual working day of ten hours is thus:

Labor, supervision, coal and supplies........	$30.56
Interest, repairs and renewals..............	28.80
Care during winter.........................	1.00
Total	$60.36

This dredger excavated, delivered into scows, and deposited in the river 138,001 cubic yards in 183 days of 10 hours, thus giving an average of 754.1 cubic yards per day of 10 hours. The average cost was thus, with allowance for repairs, renewals, care in winter, coal, supplies, and labor, both for dredger, scows, and towing tugs, 8.004 cents per cubic yard.

This excavation was in indurated material, as described above. Neither the centrifugal pump dredgers nor the orange-peel bucket dredgers referred to below could excavate this material.

Another larger and heavier dipper dredger worked during one season. This has a dipper with a capacity of 6 cubic yards, with which it excavated the indurated material, depositing it into scows in the same manner as the dredger last above described. The location of its working was such as to make it impracticable to keep an account of the amount of material moved by it during sufficiently prolonged periods to warrant an exact statement and comparison with the figures of cost of the other dredgers above given. While the amount per day excavated by this large dredger was greater, the cost per cubic yard was about the same as that shown by the smaller dipper dredger as given directly above.

Another dipper dredger, with a scoop of 1½ cubic yards capacity, worked during one season. It was quite similar to the one with the dipper of 2 cubic yards capacity, and the cost of excavating and depositing material by it was the same as stated above.

Soon after the beginning of the work on this canal, two large dredging machines were built at Buffalo, and brought by water to the canal. The designers of these machines expected that they would give effective and economical results, both in the indurated and in the softer material. The two machines were of exactly the same design and construction.

The hull is 103 feet long, 34 feet wide, and 10 feet deep. There are two decks, the upper one having sleeping and living rooms for the captain and all hands. All parts of the hull and upper works are strongly braced with heavy timbers and steel rods. The dredger is provided with large water tanks and coal hoppers. There are three anchoring spuds—two forward and one near astern. These are operated by an independent double-drum engine. There are two marine boilers, each of 150 horse-power, supplied with water by two Blake pumps. Two steel vacuum chambers are near the center of the boat, each cylindrical, 5 feet in diameter, 19 feet high. There is a hopper attached to the bow of the dredger, 40 feet long, 12 feet wide, built of I-beams covered with ⅜-inch steel.

The bottom of the hopper slopes to the center of the boat. A suction pipe, 18 inches in diameter, runs from the center of the hopper into and close to the bottom of the hull, backward 35 feet, where it connects by a Y to two pipes, also 18 inches in diameter, going to the two vacuum chambers. From each of these an 18-inch pipe leads aft to a Y, whence an 18-inch discharge pipe passes out from the stern of the boat. There are four 18-inch valves, one in each branch of each Y. These valves are separately operated by steam pistons controlled at the pilot-house. In the hopper at the entrance to the suction pipe is a cutter with four 2½-inch blades. This cutter is run by a separate double-cylinder engine. A high-pressure Blake pump, 10-inch suction and 8-inch discharge, supplies water to the hopper.

A heavy A frame, 26 feet from the bow, carries a cable passing from the engine drum to the outer end of a boom 40 feet long. This frame also carries the cables for operating the dredger bucket. This bucket is suspended from two sheaves, 30 inches in diameter, near the end of the boom. The bucket has a capacity of four cubic yards. It is of the form known as the Hayward orange-peel type, so-called from its resemblance to the peel of an orange when cut into quarter pieces. It has four triangular curved blades, which, when closed, form a tight semi-spherical bowl. When open the blades resemble sharp spades, and are so adjusted to steel arms, connecting rods and cables, that the maximum downward digging effect is produced with but slight tendency to lift the bucket until closed. The dredging is done by the main engine placed at the back of the pilot house. This has cylinders 14x18 inches and two drums 30 inches in diameter carrying the hoisting cables.

A 4-inch high-pressure Blake pump supplies water to the vacuum chambers and is regulated by pressure valves, so that it will stop acting when the chambers have the requisite pressure. A direct current generator supplies electric light.

All machinery is controlled by levers placed in the pilot house at the bow of the boat.

The dredging is done by the orange-peel bucket in the ordinary manner. This lifts the material from the bottom or sides of the excavation and drops it into the hopper, which is supplied with water by the large pump. The cutter is revolving in order to disintegrate the mass of excavated material. Steam is turned into one of the vacuum chambers, and then cold water is pumped in through a spray, condensing the steam and forming a vacuum. The forward valve is then opened and the water and excavated material drawn from the hopper into the chamber. The valve is then closed, the rear valve opened, steam turned into the chamber, forcing the water and excavated material into and through the discharge pipe. While one vacuum chamber is discharging the other should be filling, their work alternating and the discharge made practically continuous.

An orange-peel bucket with a capacity of one cubic yard had been successfully operated in excavating the soft clay from the canal near the Grasse River. This was supported on a movable platform on land. The clay was wet but not under water. It was expected that this large floating dredger would be more advantageous. It was found, however, that this large bucket was quite incapable of excavating the indurated material. It could not move sufficient to pay for its maintenance. It could excavate the softer material; but the hopper, the cutter and the vacuum method of transmission failed to transport the material with economy. It formed into balls and lumps in the hopper and did not flow with the water as suspended material but rather as small separate masses carried through the pipes. The steam capacity, though large, was not sufficient to operate the vacuums alternately with continuity, and thus, instead of a steady flow through the discharge pipe, there was an intermittent series of impulses. The attempt to use these vacuum orange-peel dredgers for this excavation was abandoned, and one of them was rebuilt as the centrifugal pump dredger with 18-inch discharge pipe, described above. The other vacuum dredger was sent to the vicinity of New York, and is working in material quite different from any encountered in the canal.

No ladder of continuous scoop dredgers were used on this work. Experience on the St. Lawrence River not very far from this locality had shown good results from such dredgers, and it is regretted by the writer that the contractors did not place at least one such in operation.

Summarizing the statements above made: The total amount excavated by dredgers in this canal was 1,436,000 cubic yards. There were in addition excavated by other means 4,433,000 cubic yards.

The vacuum pump dredgers with orange-peel buckets and pipe transmission lines were not serviceable in excavating and transmitting either the indurated or the softer material.

The centrifugal pump dredger excavating by revolving cutter to depths under water not exceeding 22 feet, lifting the material to a height of 30 feet above water and depositing it through a pipe of 12 inches diameter, 1,200 feet distant from the canal, could not excavate the indurated material but worked with success in the softer material. It excavated and deposited in three seasons 459,800 cubic yards of this material at an average cost of 8.507 cents per cubic yard, this cost including labor, supplies, coal, repairs, renewals and care during the winter seasons.

The centrifugal pump dredger, generally similar to the one last mentioned but with a discharge pipe 18 inches in diameter, working in the softer material, excavated and deposited in two seasons 290,780 cubic yards at an average cost of 9.399 cents per cubic yard. The centrifugal pump dredgers worked 22 hours of each 24 hours.

The dipper dredgers excavated during three seasons 525,306 cubic yards. This was indurated material. It was deposited in scows and towed by tugs and deposited in water about 5,500 feet from the dredgers. One of these dredgers with a dipper of 2½ cubic yards capacity, working 10 hours each day and excavating to a depth of 20 feet below the water surface, lifted and delivered 138,001 cubic yards in 183 working days of 10 hours, at an average cost of 8.004 cents per cubic yard, this cost including labor, supplies, coal, repairs, renewals and care in winter, for the dredger, scows and tug for towing.

Coal is included in these statements at a cost of $3 per ton; the modification for a different price of coal can be readily found.

In latitudes where dredging can be done during all seasons of the year the modification required can be easily made from the data above given; the cost per unit will be reduced provided also there is continuous work for the dredger throughout the year.

The Noted Burr Bridge at Harrisburg, one of the oldest in the country, is to be torn down. The piers were begun in 1812 and the first vehicle passed over it in 1816. In 1846 it was partly wrecked by a flood and in 1866 by fire. It was originally built from Theodore Burr's designs at a cost of $192,000.

Reconstruction of the Lake Winnibigoshish Dam.

Two very interesting types of movable weirs were constructed during 1900 by the Corps of Engineers, U. S. A., in carrying out the plans for the reconstruction of the dams at the headwaters of the Mississippi River. They are described in the report of Captain H. M. Chittenden, which forms a part of the report of the Chief of Engineers for the year 1900, and the following account of the work has been prepared from the description there given:

The Lake Winnibigoshish reservoir was completed in 1884 at a cost of $238,000. The dams consisted of 2,546 linear feet of low dikes, 1,009 linear feet of embankment 20 feet high above low water, and 172 linear feet of Norway and white pine timber cribwork filled with granite bowlders. The controlling works were in the latter structure. The dikes were built of fine sand and sodded and were 10 feet wide on top, having a slope on the lake side 2 horizontal to 1 vertical, on the lower side 1½ to 1, height 4.8 feet above flowage line. The embankments at each end of cribwork were also of sand, but contained a center core of puddled clay in which was embedded a 6-inch timber diaphragm. Top width of embankment, 10 feet; slopes 2 to 1. The upstream slope was covered with a 4-inch layer of clay and 12 inches of bowlders, riprap size. The embankments were carried 6½ feet above flowage.

The timbered portions of dam containing the controlling works rested on a pile foundation driven in clay. The foundation measured 172 feet long by 191 feet 6 inches wide, thus giving a wide apron. In cross section the timber dam had a vertical upstream face 19 feet high, top 16 feet wide, then a vertical drop of 9 feet, a horizontal step of 12 feet, and another vertical face 11 feet 9 inches high. The elevation of the upstream apron was 1 foot 9 inches higher than the downstream one; width of upstream apron 49 feet, base of dam 28 feet, width of downstream apron 114 feet and 6 inches, making 191 feet and 6 inches width of foundation. The upstream apron was placed 4.8 feet below low water in Lake Winnibigoshish. There were twenty-five sluices in the dam—twenty-four covered and one open for logs. Twenty-three of the covered sluices were 4 feet wide by 5 feet high, and one was 4 feet 6 inches wide by 5 feet high. The tops of the covered sluices were 0.2 foot above low water in lake and closed by ordinary sliding gates. The log sluice was 5 feet 6 inches wide and closed by stop planks.

By 1898, after fourteen years' service, the Norway pine in the cribwork had become so rotten that the timber dam became unsafe. The general deficiency act approved July 7, 1898, authorized the renewal of the reservoir dams, and the river and harbor act approved March 3, 1899, made an appropriation for the renewal of the Lake Winnibigoshish and Leech Lake dams. The reconstruction of the former was commenced in the spring of 1899 and completed in the fall of 1900. The new structure has been built on the old foundation, which was in excellent condition, but was strengthened by additional piles and lengthened about 3½ feet. The superstructure consists of two concrete abutments, five concrete piers, five steel Tainter gates and one wooden reversed Parker bear trap gate. Four piers are 11 feet by 37 feet 6 inches in plan, and the other is 12 feet 5 inches by 101 feet 6 inches. The abutments are 187 feet 6 inches long.

The concrete was made of Saylor's Portland cement, very fine sand, and crushed granite bowlders, mixed by power in a 4-foot cubical box mixer, in proportion of 1:3:6. Ninety-seven per cent. of the sand passed a No. 50 sieve and 33 per cent. a No. 80 sieve. All the stone was taken at a nominal expense from the old dam and from the dike. The stone was crushed with a jaw crusher and the entire product run to the mixer without being screened. The crushed material varied in size from dust and sand to flat spawls 4 to 5 inches square. In adding sand to the mix allowance was made for the dust and sand in the crushed stone. From three to eight small boulders were placed in each batch before going to mixer. The total amount of concrete laid was 4,444 cubic yards, at a cost of $10.72 per yard. Had the same price been paid for the rock as was paid for that used to replace the rock removed from the dike, the cost of the concrete would have been about $13.

The concrete forms were lined with No. 8 iron. All concrete was laid wet and quaky and rammed or worked with 40-pound rammers. The faces of the blocks are smooth, uniform in color, and present a fine appearance. The concrete is hard and tough. The sides of the sluices where the gates rub are lined with cast-iron plates that were adjusted to true planes after the walls were laid. The blocks of concrete were limited to 12 feet in length; adjoining blocks were doweled together. No effort was made to complete a block in one working day, and the horizontal planes between successive days' work were washed with cement grout and bonded together by bowlders half embedded in each.

The dam is situated near the outlet of a large inland lake, and when the water is high the lake extends to the dam. To avoid the injury that would be occasioned by the thrust of ice during those winters when the water in the reservoir was at a high stage, an expedient has been adopted to prevent thick ice forming above the dam. Slots for stop plank were provided in the abutments and piers close to the upstream faces. During the winter months the gates are kept open, but the sluices are closed with stop planks, except for a thin sheet of water that is allowed to escape over the top plank. This prevents the formation of thick ice.

The Tainter gates are of steel sheathed with 3 inches of oak. Each gate has five sets of radial arms, with six arms in each set, all securely riveted to a built-up steel axle having cast-steel trunnions that revolve in cast-iron journal boxes anchored to the concrete. The gates are counterweighted with concrete weights hung by chains fastened to each end of the gates, which pass over four sheaves supported by steel framework. The hoisting gears are double-purchase winches winding a five-eighths inch chain, this arrangement being separate from the counterweight mechanism. One man can hoist or lower a gate, but as the dam tender has an assistant, it is usual for two men to work together.

The principal dimensions of the gate are: width, 14 feet; height above upper floor, 19½ feet; radius, 24 feet; diameter of trunnion, 10 inches; length of journal bearing, 12 inches; vertical distance of axle above upper floor, 12½ feet.

The gate in the log sluice is a wooden reversed Parker bear-trap with forged steel hinges. The X-leaf is made of 12x12-inch Oregon fir; the Z-leaf of 6x12-inch oak; the Y-leaf of 20x12-inch Oregon fir, and the idler leaf of 9x12-inch Oregon fir. The rise of the Y-leaf is limited by twenty-four 1⅛-inch stud chains. The dimensions of this gate are as follows: length of crest, 12 feet; horizontal distance between base hinges, 55 feet; vertical height between base hinges, 1 foot 9 inches; horizontal distance between hinges on X-leaf with the gate lowered, 22 feet; horizontal distance between hinges on Y-leaf, 36 feet 10 inches; rise, 15 feet 2 inches.

Although the gate is loaded with protecting plates of strap iron and railroad rails, it is sensitive and responds quickly to any movement of the valve. The lowest head at the dam since completion of the gate has been 23 inches; it was sufficient to raise the gate, but the least head required is not known. The gate works well, coming to its final upward position easily and without a jar or jerk.

The concrete conduit for leading the water to the valve and for discharging the water when the gate is to be lowered is 3 feet 6 inches square, and built in the long pier beside the gate. The valve, which is of cast iron, is semi-cylindrical in shape, with its axis vertical, so that when turned so as to just allow the water to enter the bear trap the exit for the water from the trap has begun to close, and when the exit is entirely closed the entrance is entirely open, thus allowing the total head to act in raising the gate. The valve is very much like one of the Tainter gates placed on end. The diameter of the valve is 8 feet, and its height, or length of axis, is 3 feet 8 inches. It has been found to work very well, being turned by a worm and wheel gear placed on top of the pier. A slight pressure on the hand wheel suffices to turn it, and by adjusting the position of the valve the bear trap can be held in any desired position within its range of motion, thus giving an easy and complete control of the discharge.

After having been in service for nearly a month, and having been operated many times, a few minor defects became apparent in the details of the bear-trap gate, which it was deemed advisable to correct. Accordingly, the area occupied by the gate was surrounded by a bulkhead and pumped dry. The observed defects were then removed, and since that time the gate has worked admirably.

The various operations connected with the reconstruction of this dam were carried on in the following order: After clearing away the old dam and preparing the foundation the concrete work was begun. When the concrete portions of the structure were finished, work was begun dismantling the derrick and plant for storage or removal to the Leech Lake dam, which was also being reconstructed at that time. The Tainter gates and also the log sluice gate were then put in place, and in the last of August, 1900, pumping was stopped and the cofferdam allowed to fill. At the same time the pulling up of the sheet piling of the cofferdam was begun, the object being to run the water through the new dam as soon as possible in order to permit the closing of the cut through the dike, through which the Mississippi River flowed during the reconstruction. Timber trestles were placed in the Tainter gate openings to support the gates during erection, and at the same time permit the passage of water. The erection of the gates began toward the last of September, and the steel work went together without trouble, very little drifting being necessary.

The dike through which the temporary cut was made for the river to flow through is 20 feet high above low water in the lake with slopes of 1 on 2. There is a wooden diaphragm of 6-inch sheeting reaching just above the flowage line and surrounded by a well-compacted clay puddle wall about 14 feet wide at the base and 5 feet wide at the top. This timber diaphragm is very well preserved by the clay. The cut through the dike was 100 feet wide at the water surface, and over 6,500 cubic yards of sand and clay were used in filling.

The construction of the concrete counterweights for the Tainter gates was the last work performed during 1900, and the weather had grown so cold by that time that the recesses between the piers were roofed over and the inclosure kept warm by stoves. All work on the reconstruction of the dam ceased about December 1, and there still remained to be done in the spring of 1901 the installation of the cranes for raising the stop planks, some minor work upon the gate hoisting machinery, and the building of booms to protect the dike from waves. This work was started with a small crew on May 14.

The cost of the reconstruction of the Lake Winnibigoshish dam, exclusive of superintendence, office expenses and repairs to the wagon road between the dam and the nearest railway station (11 miles distant) is itemized as follows: Buildings, including cement house, \$5,304.91; plant, \$9,162.95; cofferdams, \$16,301.40; embankments, \$10,380.42; repairs to old foundation, \$23,213.29; concrete at \$10.72 per cubic yard, \$47,664.21; five Tainter gates and one bear-trap gate, \$27,053.60; piers and booms above dam and embankment, \$5,029.41; making a total expenditure up to the end of 1900 of \$144,110.19.

In addition to above, but not included in the cost of reconstruction, the upstream slope of the embankment has been re-covered. The 12 inches of riprap stone did not protect it against wash and scour by rain and wave action. The interstices between the stones appeared to be too large, and it was thought best to place next to the 4-inch layer of clay 6 inches of broken stone and then a layer of bowlders 16 inches thick at the bottom of the slope, tapering to 4 inches at the top of the embankment. A further protection against wave action was provided by a floating timber boom 14 inches deep by 54 inches wide, supported by piles driven into the overflowed bottom lands a short distance above the toe of the embankment. With the exception of the slope covering, the embankments were in first-class condition. The timber diaphragm in the puddled clay core was remarkably well preserved.

As supplementary to the preceding description it may be of interest to give a brief history of what is known as the bear-trap gate or dam. The first to bear this name was built in 1819 by Josiah White on the Lehigh River in Pennsylvania, as a means for the improvement of navigation in the interests of the Lehigh Navigation Company. The following quotation from the "History of Lehigh and Carbon Counties, Pennsylvania," by Alfred Mathews and Austin N. Hungerford explains the situation:

"They [Josiah White and Erskine Hazard] found that they had been misinformed in regard to the lowest point reached by the river, and that the natural flow of the Lehigh was insufficient to give 18 inches and a width of 25 feet as was required by law, and hence they were obliged to resort to the plan of producing artificial freshets. For this purpose a peculiar sluice was needed, and Josiah White devoted himself for several weeks to the work of constructing one, finally producing what came to be known as the 'bear-trap.' He built a miniature experimental sluice in Mauch Chunk Creek, and the name 'bear-trap' was given to it by the workmen who were annoyed by the curious as to what they were making.

"During the year 1819, twelve of these dams and locks were built and the managers fully proved their ability to send to the market, by the artificial navigation, such a regular supply of coal as would supply the demand."

In the "Journal" of the Association of Engineering Societies for June 1896, there was given a complete history of the bear-trap dam, including the analyses of the later forms, from which the following extracts have been taken:

The design of the bear-trap did not receive from American engineers the support that it was entitled to, perhaps because the development of our internal waterways on a large scale was not undertaken until after the French had made an unfortunate construction of one on the River Marne, and forthwith condemned it. The experience in France was widely published and served to prejudice our own engineers.

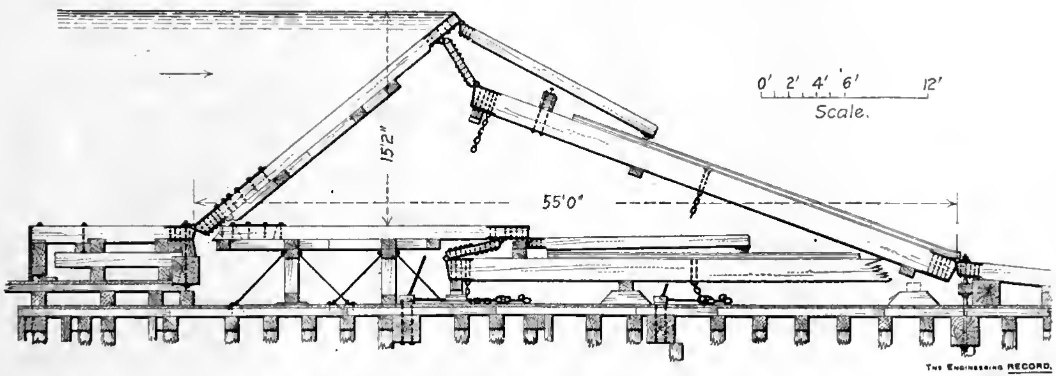
In 1862, Mr. John Du Bois, of Williamsport, Pa., patented a modification of White's design. Mr. Du Bois' gate was followed in France in 1870 by a device of M. Carro. Neither of these alterations were improvements on the prototype. In an attempt to improve on the old bear-trap, Hon. Felix R. Brunot, of Allegheny, Pa., patented in 1867 a "sluice gate for dams and locks."

Mr. Ashbel Welch, the twelfth president of the American Society of Civil Engineers, was one of the first engineers to place confidence in the structure, and the next well-known engineers to look with favor upon the bear-trap were a board of United States officers, who in 1883-4 recommended its adoption at the Beattyville dam on the Kentucky River. Here two gates, each 60 feet long, were built in 1886. In 1888-9 a drift pass 52 feet wide in the Davis Island dam on the Ohio River was closed by a bear-trap, and was in constant use after that time.

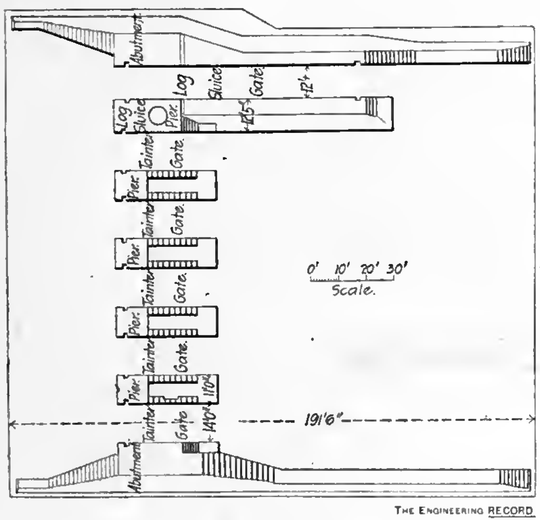
No positive advancement was made over Mr. White's pattern until 1887, when Thomas Parker, of Menomonie, Wis., received a patent for the improvement that marks an era in the development of bear-trap gates. Mr. Parker sought to minimize the two chief defects of the old form, which were friction between the two leaves and the inability to construct a high dam upon a short base.

In 1890 appeared the device of Robert A. Lang, of Eau Claire, Wis., in which he substituted chains and rods for the upper one of Parker's folding leaves, and converted the idler into a functional part of the weir. This, however, is thought by some to be a retrograde step, as introducing more friction. Major Marshall had studied the same idea previously.

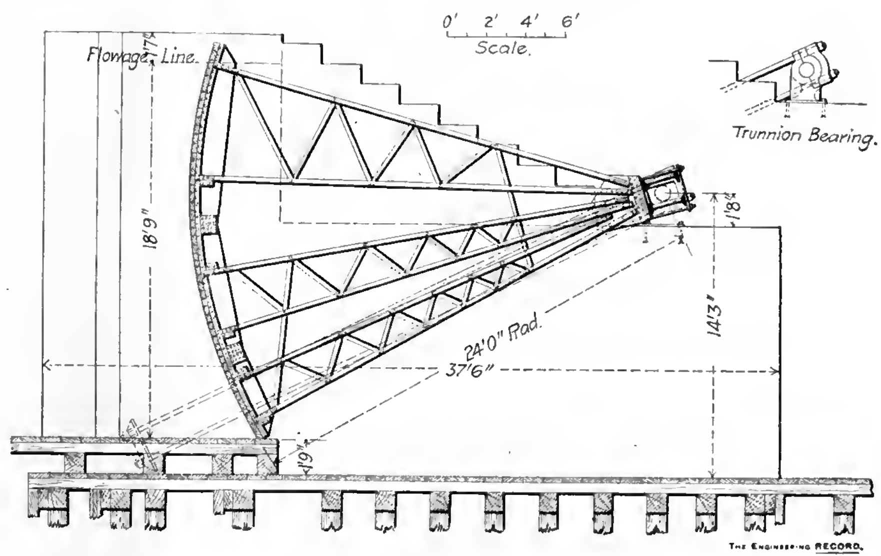
Horace Harding, U. S. Assistant Engineer in the Mobile district, planned a reversed Parker, minus the idler, for a lock gate in 1892. Since then several have independently proposed the same change. In 1892, H. M. Chittenden and A. O. Powell, of the U. S. engineer corps, were detailed to investigate the subject of the forces brought to bear on the gate, and their two analyses are given in the issue of the "Journal" of the Asociation of Engineering Societies from which this history has been prepared. Later developments of the bear-type are more or less well known to engineers, and will therefore not be given here.



THE REVERSED PARKER BEAR-TRAP GATE.



PLAN OF GATES, WINNIBIGOSHISH DAM.



TRANSVERSE SECTION OF ONE OF THE TAINTER GATES.

Relation Between Macadam Roads and Electric Street Railways.

A paper read at the Third Annual Good Roads Convention at Albany by Edward P. North, M. Am. Soc. C. E.

No one can look at the returns of the last census without concern for the future of our rural districts, and consequently on the future of this State. The rewards offered to ambition in 22 counties in this State have in the past ten years grown relatively, if not absolutely, less, and they are being depopulated. The list of those counties, with their population in 1900 and the loss since 1890, is given as follows:

Counties.	Population in 1900.	Loss since 1890.
Allegheny	41,510	1,739
Chenango	36,568	1,208
Columbia	43,211	2,961
Cortland	27,576	1,081
Essex	30,707	2,345
Greene	31,478	120
Lewis	27,427	2,379
Livingston	37,059	742
Madison	40,545	2,347
Orleans	30,164	639
Oswego	70,881	1,002
Otsego	48,939	1,922
Putnam	13,787	1,062
Rensselaer	121,697	2,814
Schoharie	26,854	2,310
Schuyler	15,811	900
Seneca	28,114	113
Tioga	27,951	1,984
Washington	45,624	66
Wayne	48,660	1,069
Wyoming	30,413	780
Yates	20,318	683
Total	845,294	30,266

That is to say: In the 22 counties mentioned there has been a decrease in population of over 3½ per cent. during the past ten years. In this period the State as a whole has gained 1,270,159, a gain of 21.2 per cent., but the gain in cities of 25,000 inhabitants or more has been 1,268,769, so that the gain in our population has been almost entirely made in cities.

In the city of New York, comparing equal areas, the increase between 1890 and 1900 has been from 3,437,202 to 4,507,414, or 1,070,212, which nearly accounts for the net urban gain, some cities of 25,000 and over having lost population.

It will be noticed that of the five counties on the east side of the Hudson from Putnam to Washington, inclusive, all but Dutchess have lost population. The increase in that county, 3,791, is offset by a gain in the population of Poughkeepsie of 3,859. The net loss to the five counties is 3,065 inhabitants.

Comparing our condition with the whole country and neighboring States, we find:

States.	Population in 1900.	Ten years increase.	Pro rating of increase.
United States	76,303,387	12,937,008	20.7
Connecticut	908,420	162,162	21.7
Massachusetts	2,805,346	566,403	25.3
New Jersey	1,883,669	438,736	30.4
New York	7,268,894	1,270,159	21.2

The comparison shows that among the States only Nevada has lost population. In Connecticut there has been a loss in Tolland County, which lies east of Hartford, of 558. In Massachusetts there has been a loss in two counties—Barnstable 1,346, and Nantucket 262; the first of these is east of Buzzards Bay, including Cape Cod, the other is an island. There has also been a loss in two counties of New Jersey—Burlington 287, which lies south of Trenton and east of Camden, and Hunterdon 848, which lies southeasterly from Phillipsburg.

A more intimate knowledge than I possess is requisite for an ex-cathedra statement as to the causes that have reduced the rewards of enterprise and made a decrease in the attractiveness of the above mentioned 22 counties as a place of residence, and there is a promptly acknowledged inability to prescribe a certain specific for the difficulty. But it is competent, and seems highly desirable, to call the attention of this body to the facts enumerated, and ask a serious study by individual members to be followed at a later meeting by a classification of the facts found which relate to and govern this extremely unsatisfactory movement in our population.

As there is difficulty in arranging any series of facts, or even in looking for them without the aid of some theory, even if it is to be promptly discarded, it is suggested that the inquiry should be commenced on the supposition that lack of convenient and cheap transportation may be the governing factor in these changes of population.

There can be little doubt in any mind that cheap and rapid transportation, affording convenient access to large markets, controls the position of large industries; or, in other words, these will be located where the cost of assembling the raw materials for manufacture and distributing the finished products is the smallest. The high cost of wagon transportation over unimproved roads now precludes profitable manufacturing at the site of the numerous small powers once used, and it is doubtful if they will ever again be employed as they were fifty years ago, diversifying the industries of the country districts, and making first-class mechanics of nearly all farmers' boys.

The occupation of the country by farmers and by those who are not obliged to be in some town every day, with those suburbanites who are known as commuters, stands on a different and more hopeful basis. Farming is an occupation that is generally pursued for gain rather than for the sake of unremunerated labor. But the farmer is confronted with the fact that while all cost of transportation must in some ratio be divided between the producer and consumer, he generally sells in a nearly satisfied, if not glutted, market, where the cost of transportation falls on him, so that he in general is the heaviest loser by roads over which the cost of haulage is excessive.

When his day's work is done he joins his wife and children in the leisure class, and becomes, like the commuter, dependent on the ease with which he can reach the various centers of interest near him; and good macadam roads have already proved their value in keeping the farmer's family contented in their home, as well as increasing the net rewards of their labor.

The choice of residence by commuters is governed by mixed considerations of time, cost and attractiveness of locality, and good roads are a weighty factor in the attractiveness of a locality. It is probably because New Jersey commenced building macadamized roads about thirty years ago that the State is able to show a 30 per cent. increase in her population, while the five counties east of the Hudson and north of Westchester, without improved roads, show a net loss of slightly more than 1 per cent. This, however, is not entirely due to the absence of improved roads; it is claimed that the railroads extending north and south through these counties take less pains to develop their commuting traffic than do the roads through either New Jersey or Connecticut.

Some theories of this kind seem necessary in accounting for decreased population in a beautiful and healthy country near to and closely connected with the largest and richest city on this continent, whose business men are filling up the near-by counties of New Jersey and Connecticut.

If we assume that the average wealth of inhabitants of this State is equal to that of the average inhabitant of the whole country, as stated by the Treasury Bureau of Statistics, namely, $1,235.86 per capita, the withdrawal of 30,266 persons from country homes in this State implies a loss of over $4,000,000 to the localities from which they moved.

Judging from a limited experience, it may be safe to say that a good road will attract both residents and business. These make the road attractive to trolley companies, and a trolley road, obviating the necessity of getting out either a horse or wheel, makes the locality still more attractive to residents and business.

It is well known that in many parts of Europe the inhabitants congregate in small villages, walking miles to their farms, and it is probable that under the improved ease of circulation presented by trolley cars the population of the country will concentrate on roads occupied by them. When any such development occurs the trolleys will be double tracked, and the value of a road of ordinary width for traffic by wagons, etc., will be greatly impaired, if not destroyed, as the wagon traffic is becoming more dense and more important to the locality.

On Fifth avenue, in the city of New York, the traffic has outgrown the capacity of the wheel way, and it must be widened at a great cost. In London the widening of Cheapside and Newgate streets was completed about ten years ago, and it is claimed that the operation must be repeated on Cheapside, as that thoroughfare is again overcrowded. These widenings have been accomplished at what was held to be prohibitory cost, on account of the destruction of the buildings fronting on them. Like widenings will undoubtedly be necessary on most of the roads that are to be macadamized in this State, and they should be completed before improvements add materially to their cost.

The feeling of antagonism to trolley roads, which destroy a newly made macadam and permanently impair the usefulness of the road for wagons, automobiles and wheels, should not make us forget their great value in distributing population. At the same time the companies exploiting them should be required to join the local authorities in widening all roads used by them. In some parts of Massachusetts the entire cost of widening roads has been thrown on the trolley company. This may not be entirely just. The question, however, should receive the study of this convention, both now and hereafter; for such a distribution of the cost as shall not impede trolley building to the loss of the country inhabitants and real estate values, and at the same time be just to the property owners, cannot be made without consideration.

The Septic Sewage Disposal Works at Red Bank, N. J., have been in operation since May. The sewage flows first into a covered grit basin, installed in duplicate to catch all sand and large substances. It then passes into a covered resolving tank 43 feet in diameter and kept filled to a depth of 9 feet. The sewage enters and leaves the tank about half way between the top and bottom. From the tank the septic sewage passes to the bottom of two covered upward filters 12 feet in diameter and 6 feet deep, which discharge into an effluent pipe running to the sewer. The plant was designed by Dr. Adolph G. Brown.

The Sanitary Inspection of the Watershed of the south branch of the Nashua River above Clinton, Mass., has been carried on in a systematic manner, according to the report of the Metropolitan Water and Sewerage Board, preparatory to the storage of water in the Wachusett Reservoir. The watershed has been divided into districts, according to the natural drainage lines of the brooks, and a careful inspection of each district has led to the removal of many cases of pollution arising from defective house drainage and other causes. A constant inspection of the camps of the laborers and of other buildings within the reservoir basin has been made by the medical inspector, and very few cases of contagious diseases have occurred.

An Investigation of a Garbage Crematory.

Extracts from a report by Rudolph Hering to the Special Committee on Crematory of the City Councils of Trenton, N. J. A comment on this report is printed on page 241.

The base of the furnace is placed one story below the street level, so that the garbage can be readily delivered from the street to the floor level above the furnaces, and easily be fed to them through openings in the floor. The furnaces and feeding floor are enclosed in a brick building, apparently well and strongly built. The crematory is of the Davis type, and consists of two complete garbage furnaces connected by separate flues to a single chimney stack. The chimney is built of brick, has an internal section 5 feet square, and is about 120 feet high above the base and about 100 feet above the entrance of the flues. In the stack are a set of screens of ½-inch mesh, for the purpose of intercepting dust and larger particles escaping from the fires, and also a regulating damper which can be operated from a point near the feed holes.

Each furnace consists of:

1. An arched drying chamber, 8 feet square and 8 feet 6 inches high to the key of the arch, into which the garbage is dumped through a feed hole. It is provided with grates, chiefly for drainage purposes. The garbage remains in this chamber during the process of draining and drying, and at intervals it is raked down with long iron rakes into the combustion chamber.

2. An arched combustion chamber, 4 feet long, 6 feet wide and 4 feet high to the key, placed in front and approximately at the same level of the drying chamber. It is provided with grates on which coal is burned to assist the burning of the garbage which the attendant rakes down from the drying chamber.

3. A main flue about 3 feet wide by 3 feet 6 inches high, leading from the furnace to the chimney stack.

4. An arched secondary flue, 4 feet 6 inches long by 5 feet 4 inches wide and 3 feet high, in which is situated a set of fire grates about 2 feet long and 4 feet wide, and on which auxiliary fires are kept burning ostensibly for the purpose of completely eliminating odorous fumes on their way to the stack.

5. A so-called evaporating pan, under and of the same area as the drying grate, into which the liquid from the garbage freely drains. Some of this liquid may be evaporated, but most of it is led off by a 4-inch drain pipe to the sewer in the street.

6. A feed hole or opening above the drying chamber, through which the garbage is dumped. It is closed with a movable iron cover.

7. Grate bars, about 4 feet long and 4 inches wide, the openings between which are ½ inch wide for the fire grates and ¼ inch wide for the drying grate.

8. Ash pits under all grates, and firing and observation gates or doors complete the chief parts of the installation.

The chimney stack, the furnaces themselves and their parts appear to be built of good material and indicate good workmanship. The station appeared to be kept clean and in good order.

The City's Refuse.—The city's refuse may be classified as follows:

1. Ashes, bottles, cans and other non-combustible material, which is collected and disposed of by tipping and filling at various places in the city.

2. The garbage proper or house refuse, being largely of combustible nature and also known as "swill" or "slop," containing at the present season much fruit and being almost saturated with water, is collected and delivered at the crematory by the city in special garbage carts.

3. Garbage and refuse from stores, markets, etc., is collected and brought to the crematory by private parties. Much of it is of a very combustible nature, such as paper, rags, straw, wooden boxes, etc.

The collection and disposal of the first of these classes, apparently not causing any trouble, has not been considered in this investigation. The disposal of the garbage and refuse mentioned as the second and third classes has been a cause, however, for serious complaint, and to this the investigation is limited. Speaking generally, the sources of the troubles complained of may be stated as follows, and are subsequently discussed under separate headings: 1. Collection of garbage and odors arising from it when delivered at the works. 2. Odors from the ashes after their removal from the furnace when retaining some incompletely burned material. 3. Dust of completely burned garbage escaping from the stack and depositing in the neighborhood. 4. Unburned or still burning particles of garbage escaping from the stack and depositing in the neighborhood, with the possibility of falling upon shingle roofs or inflammable material and thereby causing fires. 5. Odors due to the unburned gases escaping from the stack.

Collection of Garbage and Odors Arising When Delivered at the Works.—The city garbage is collected in iron carts of approved make, holding about one ton and drawn by two horses. The carts collect from all parts of the city, daily except Sunday, and between the hours of 6 A. M. and 6 P. M. Each one serves a certain district, the number of trips being of such frequency that each house is visited as many as two or three times each week, according to the season. The carts are watertight, sanitary in every way, and so far as we know have not given any offense. The private garbage and dry refuse is brought to the crematory in the ordinary store wagons. We were not made aware that such collections had given any offense. The dry refuse, such as paper, wood, rags, etc., is generally collected from the houses in large bulk, while the garbage proper is first put into pails, boxes or barrels, usually left open, and subsequently collected by the teams.

On arriving at the crematory the contents of the carts and wagons are immediately dumped into the furnaces, unless these are already charged to their full capacity, in which case the wagon is detained or left standing until one of the furnaces is in a condition to receive the charge.

The only odors which may arise from the present method of city collection, can be caused by the often improper and usually open receptacle, but chiefly by the occasional filling of the carts beyond their normal capacity, so that the lids do not close, and odors may be given off while the carts pass along the street. The same objection may apply also to the private wagons for collecting garbage, but so far as we know, complaints have not been made.

These sources of trouble are easily prevented by proper municipal regulations and due care. Among the other essentials to prevent offensive odors from arising before the material is subjected to the burning process, are frequent collections of the garbage in proper vehicles, both of which you have already provided for very satisfactorily.

Odors from Ashes After Removal from Furnace When Retaining Some Incompletely Burned Material.—Offensive odors arise when the ashes are removed from the grates and deposited in exposed places before the garbage is thoroughly burned. This trouble is especially likely to occur with a crematory like yours, located in the midst of a thickly settled district where such odors are more readily noticed than in remote districts.

On the day of our first visit to your crematory there was a strong odor emanating from the pile of clinkers or ashes which had been dumped in front of the building. An examination showed that it was due to quite a number of unburned pieces of animal and vegetable refuse. This annoyance clearly cannot occur if the garbage is so thoroughly consumed upon the grates that nothing but clinkers and ashes remain when their removal from the furnace is necessary.

The remedy for the defect is therefore clear. 1. The furnace must be in a condition to be capable of completely burning the organic matter, of which more will be said below. 2. The attendant must be very observant and attentive in not pulling out anything but thoroughly burned material.

This inattention has at other places been a frequent cause of objectionable results and therefore of complaints. Too generally it is supposed that any stoker or fireman quite familiar with handling coal fires is also able to handle garbage fires. The latter, due to the presence and mixture of the greatest variety of combustible and noncombustible matter, are very much more difficult to operate than simple coal fires. When starting the furnaces in Hamburg, the most extensive garbage plant in the world, and also the experimental furnaces in Berlin, it was found necessary to import firemen from England, where crematories have been in use for fifty years, in order to train the German firemen in the special art of garbage cremation. It is an art that requires experience, skill and a faculty for constant attentive observation, which can be acquired only under skillful guidance by continued practice of intelligent and faithful men.

Dust and Burned Garbage Escaping from Stack and Depositing in Neighborhood.—When garbage is carefully burned and the combustion is complete, there may yet be trouble from the fine ashes of paper, wood, rags and other organic matter escaping from the stack and being carried with the wind to greater or less distances, even entering windows and causing dirt and consequent annoyance.

This nuisance is chiefly due either to faulty design of the flues or chimney, or to improper manipulation of the draft, or to both. In fact, ashes should not be carried up into the stack at all, but be deposited in enlarged flues or dust chambers on the way to the stack. These chambers should be given a relatively large sectional area, in order that the velocity of the fumes may be retarded and the heavier dust particles settle out, thus leaving practically the gases alone to pass freely out through the stack.

Even if the flues and dust chambers are properly designed, improperly designed dampers or their careless manipulation may also be the cause of this trouble. Dampers should have the full size of the flues, and be provided with simple mechanism so as to be easily operated from the fire-room or from a point near the feed hole. They should be always closed when the feed hole is open for charging the furnace, and also whenever the furnace doors are open for the purpose of firing, stoking or cleaning. That is, they should be almost tightly closed, leaving only enough draft so that fumes do not rise into the building from the feed hole or furnace doors. In general, they should always be under such careful control and so manipulated that the velocity of the gases in the settling chamber and the flues can be maintained below a certain required maximum rate. What this maximum rate should be, permitting the dust particles to settle, we are not able to state with desirable definiteness, because the data are meager concerning such deposit, which depends upon the size of the particles and their specific gravity; the finer and lighter the particles of course the more readily they are kept afloat in the moving gases.

It may, however, be safe for practical purposes at present to estimate that the velocity of the current through the dust chamber should be kept as low as from 1 to 1.5 feet per second. In order to secure this reduced velocity, we must first know the volume of gas which passes through the dust chamber in a given time. It is a variable quantity and depends on the chimney draft and the manipulation of the dampers. With the proper grate area for the burning of thirty tons of garbage per day, we may, however, roughly estimate the volume of air required for the combustion as being about 150 cubic feet per second. This would therefore require a sectional area of at least 100 square feet, or more than four times the combined area of the present flues. To facilitate further the deposition of dust it is an advantage to have the level of the inlet as far as possible below the level of the outlet, so that the force of gravity, slight as it would be, can favor rather than hinder the tendency for the dust to deposit.

The construction of a dust chamber of ample dimensions, placed between the furnaces and the stack, and properly designed dampers, would very materially, and with careful manipulation in accordance with the momentary conditions of the openings at the feed hole and gates, probably wholly, remedy the defect discussed under this heading. The chamber should, however, be constructed with a sufficient number of baffles to secure a uniform reduction in the velocity, not allowing the gases to pass through more quickly in the center than along the sides.

Unburned Particles of Garbage Escaping from Stack.—The effects of completely burned particles of garbage escaping from the stack have just been described. The annoyance from the partly or wholly unburned particles now to be considered is more aggravated, owing to their charry or greasy nature, and, as they are heavier, also to their tendency to settle more quickly and therefore more densely in the immediate neighborhood of the crematory. There is forthcoming the possibility of still burning or glowing particles setting fire to roofs or to inflammable material in the streets or yards.

To determine the extent of this nuisance, careful observations were made, and it was observed, almost without exception, that particles of black charred paper and similarly light material escaping from the stack could be seen at intervals during a whole day. They were apparently more numerous shortly after the furnace doors or the feed holes were opened, which naturally caused an increased draft through the flues and chimney. The damper, which is supposed to be closed during the feeding of garbage to the furnace, was not always operated with the necessary ease during the days of our inspection.

To determine how far-reaching this nuisance was in the neighboring districts, observations were made at distances of one-quarter, one-third and one-half a mile from the crematory, during one afternoon when the conditions appeared to be normal. The day was clear, and the wind was blowing at an estimated rate of about ten miles per hour. At a distance of one-quarter of a mile from the stack, about fifteen charred particles were observed in ten minutes to pass a plane at right angles to the direction of a moving smoke. At a distance of about one-third of a mile about ten particles passed in ten minutes, and at a distance of two-thirds of a mile two particles passed in ten minutes. The size of these particles varied from one-quarter of an inch to three-quarters of an inch square, averaging probably less than one-half an inch square.

Further observations were made by selecting places in fields, where the ground was sufficiently open to aid one in finding particles which might have previously settled on the ground. These places were selected always in the line of the moving smoke. The sizes of the particles were about the same as those first mentioned. At a distance of about two-thirds of a mile from the crematory, and after searching for about fifteen minutes, two charred particles were found on an area of fifty feet square. At a distance of one-third of a mile, after the same interval, eight particles were found on an area of about fifteen feet square. For how long a period these particles had accumulated cannot be stated. As a heavy rain had fallen during the previous night, sufficient in all probability to destroy traces of particles previously deposited, and as the wind had been in the same quarter only during the afternoon, it seems probable that these particles were the accumulations of only a few hours.

Observations were also made regarding the escape of burning embers from the stack. They were best undertaken at night, while the crematory was yet in full operation and when the burning particles were readily visible. On each of two nights, and extending over periods of from two to three hours, the burning particles from the stack were closely watched with the following results: 1. No embers were seen in a flaming condition; 2. Glowing embers were generally emitted after opening of the furnace doors for firing, cleaning or raking down the garbage. 3. During these times it was estimated that an average of fifty to one hundred sparks were emitted per minute. Of these it was further estimated that fifty per cent. did not travel in a glowing state more than 25 feet from the top of the stack, ninety per cent. not over 50 feet, ninety-five per cent. not over 75 feet, ninety-nine per cent. not over 100 feet, and rarely one could be seen 150 to 200 feet. From these observations it is evident that the trouble from escaping particles of unconsumed garbage is a serious one, and worse than if merely burned dust escaped from the stack.

In seeking for means to remedy this defect, we must carefully inquire into its two prime causes, namely, the incomplete combustion in the furnace and too great a velocity of the fumes in the flues.

Odors Due to Unburned Gases Escaping from Stack.—The stench resulting from incomplete combustion is usually the most serious trouble that arises from garbage cremation, and it is the one which in our country does not seem to have as yet been completely solved at any one of the principal garbage furnaces. It is my opinion, in addition to what has already been said, largely due to the design of the furnace.

A fruitful discussion of this subject must necessarily be divided into a careful examination of: 1. The character of the material delivered, its composition, moisture and combustible matter. 2. The essential parts of the furnace to obtain a complete combustion of such material. 3. The manipulation of charging, discharging, regulating drafts, etc.

1. The Material Delivered.—The burning quality of garbage depends principally upon three things: the amount of combustible material which it contains, the amount of fine material or dust, chiefly of an incombustible nature, which fills the pores and obstructs the free access of air, and the amount of moisture. Garbage which is poor in combustible material will not readily burn under any conditions, and garbage though rich in combustible material may yet be so filled with moisture as not to burn without previous drying, or the interstices may be so completely filled with fine ashes or dirt that combustion is retarded and even prevented by the lack of air.

In European cities, where garbage and city rubbish is mixed also with ashes, the combined refuse is comparatively dry, and the percentage of unburned coal in the ashes, together with the combustible matter of the garbage itself, is sufficient in properly constructed furnaces to burn without the addition of fuel. In our country, however, there are many cities, as Trenton, where it has become the practice to separate the ashes and the garbage. The burning then may become a more difficult matter and ofttimes can only be accomplished by the addition of fuel.

Regarding the propriety of separating the refuse substantially into ashes, dry rubbish and kitchen garbage, much can be said on both sides. The wisdom of separating the ashes in Trenton from the rest of the refuse, under the present circumstances, should be considered only from the economical point of view. That is, would the amount of unburned coal remaining in the ashes after sifting make it unnecessary to purchase clean coal for assisting the fires in the furnace, and would the total expense of delivering the ashes at the crematory, of sifting them and subsequently disposing of the siftings, be less than that of the present method? I am not prepared now to answer this question, as it would require an investigation much larger than was necessary for present purposes, and was not undertaken also for the reason that the installation of the furnaces is not sufficiently large to treat the great bulk of clinkers, slag and ashes that would thus be added to the fires and also require temporary storage.

To compare the garbage of Trenton with the same class of refuse in London, Berlin, New York and Boston, of which I have the information, Table I is presented, showing the various percentages of material of which garbage is generally composed. The table gives only a partial list of the material which in some of these cities were quantitatively determined, and includes only the garbage proper for the purpose of comparing it with that of Trenton.

The table shows that the garbage of Trenton is not very different from that of other cities, being as rich as any in combustible matter. The percentage of moisture, however, is very high,

Table I.—Percentage Composition of Garbage in Certain Cities in Europe and the United States, Excluding Ashes, Coal and Non-Combustible Rubbish.

	London.	Berlin.	New York.*	Boston.	Trenton.
Authority	Codrington.	Bohm & Grohn.	Craven.	O'Shea.	Special Committee on Garbage.
Kitchen garbage, animal and vegetable matter	77	82	64	84	84
Paper		11	28		12
Rags, clothing, carpets, etc.	23	3		16	3
Boxes, barrels and other rubbish		4	8		1

*Excluding Brooklyn.

and though reliable data concerning this point are not available for all of the cities, I have reason to believe that it is higher than in any of the other cities given in the list. This of course is an important matter in any process of disposal by combustion.

Let us take, for instance, the thirty-one tons of garbage delivered in Trenton per day, with 81 per cent. moisture. (See Table II.). This quantity will therefore contain approximately 24 tons of water which must be eliminated in the furnaces either by draining or evaporating before the garbage can be completely burned. Assuming that all must be evaporated in the furnaces, and taking as a basis the usual value of ten pounds of water evaporated per pound of coal, it will require 2.4 tons of coal to evaporate this water. The twenty per cent. solid material in the garbage, about ninety per cent. of which is combustible, will daily yield roughly 6 tons of dry combustible material. With a conservative calorific value of one-third that of coal, this gives an equivalent of 2 tons of coal, thus leaving a net average amount of about 0.4 ton of coal which must be added daily to consume the garbage with its present quantity of moisture. The amount of coal now actually consumed per day was found to be 2.3 tons. It is therefore clear that the arrangement of the furnace or the manner in which is is operated, or both, are not economical. At certain seasons when the garbage is not so moist as now, it seems that less or even no coal, except to start the fires, may be needed other than on rare occasions.

Table II.—Results of Operation of Garbage Crematory at Trenton for Week of Aug. 4-9, Inclusive, 1902.

Total garbage burned, tons	188.0
Garbage burned per day, tons	31.3
Coal used on main fires, tons	10.7
Coal used on auxiliary fires (estimated), tons	3.0
Total coal used, tons	13.7
Coal used per day, tons	2.3
Garbage burned per ton of coal, tons	13.8
Approximate number of hours burning each day, average	14.0
Equivalent number of days of 24 hours for the week	3.5
Equivalent garbage burned per sq. ft. of grate area per day of 24 hours, lbs	1,080
Equivalent amount of garbage burned per cell of 25 sq. ft., per day of 24 hours, tons	13.3
Estimated total amount of clinkers from garbage and coal grates, tons	14.0
Estimated total amount of ashes from below grates	3.0
Estimated total amount of ashes and clinkers, tons	17.0
Per cent. of ashes and clinkers to garbage burned, tons	9.1
Range of temperature of flue gases in stack (estimated), deg. F	600-1,000
Percentage of moisture in garbage	81.0
Corresponding water evaporated daily in furnaces, tons	25.5
Amount of coal required per day to evaporate this water on basis of 10 lbs. water per lb. coal, tons	2.5

Our observations show that much of the water which is brought with the garbage and settles to the bottom of the carts, percolates through the drying grate into the evaporating pan, which was quite filled with perhaps half a ton of water. To evaporate all these drippings would require a considerable amount of heat.

It is clearly more economical from a calorific point of view, to prevent this large amount of water from getting into the furnace, than to let it first pass through what is supposed to be the drying chamber and then into the sewer. It is quite proper, and it is the custom in many places, particularly in Europe, to dump the garbage on the floor around the feed hole, not only to mix the material properly for burning, as will be mentioned later, but to let what water will drain off go directly into the sewer. The economical as well as beneficial effect of this prior draining during at least a large part of the year will be quite noticeable.

I am satisfied that the calorific value of this garbage is such that its complete combustion could be secured with a much smaller amount of coal than is now used. To obtain this result, it will be necessary to operate the crematory along the lines already mentioned with a view of preventing a nuisance, and to have a furnace in which the combustion of the garbage can be more economically obtained, i. e., to insure complete combustion without excessive loss of heat. It remains, therefore, to examine into the essential parts of

2. The Garbage Furnace.—Although the nature and composition of garbage affects greatly the relative burning qualities in any furnace, the successful burning in any case will depend primarily upon the construction of the furnace itself. Garbage furnaces in England, where they have been used for half a century, are usually divided into small units called cells, in a manner similarly to a battery of boilers, and are arranged in pairs straddling a common main flue. Each cell has a separate connection with this flue and is operated independently of the other cells. The grate area of one cell is usually 25 square feet, this being the size which has been found to be most conveniently and economically operated. The grate bars are usually detachable and have an effective air space of about 25 to 30 per cent. of the grate area. They are usually inclined to the front so that the garbage from the feeding hopper can slide down or be raked down upon them. The chamber over the grates is of ample size, longer than the grates, and slopes with the grate surface. Over the upper end of this incline is the hopper and opening for receiving the garbage. As it burns away on the grate below, the raw material above slowly slides down to take the place of the consumed material. While descending, it is subjected to the influence of the heat from the fire in front and gradually dried and then automatically ignited. The stoker observes the process and aids it by properly pulling and spreading fresh material at the rear and drawing out the hard clinkers and ashes in front.

The gases and hot air pass into flues usually above the grates, and then into a settling chamber where the dust particles deposit. Then they again enter the main flue and pass through the chimney. Generally the gases also pass through a so-called fume-cremator, where they are reduced to an inodorous condition. In some European refuse destructors, as they are called, the heat of these gases from the main flue is utilized in making steam for power or electric lighting. To aid combustion forced draft is frequently resorted to, either by steam jet or air jet, the jet entering under the grates of the furnace. It is found greatly to increase the burning. Dampers are placed on the main flues and on the flues connected with each cell. The latter are always closed during the process of firing, raking or cleaning of a cell. Ash pits and cleaning doors are provided under the gates of each cell, also cleaning doors at the settling chamber, flues and chimney.

American garbage furnaces differ essentially from the European in that the grate surfaces are much larger and practically horizontal. The result of this practice is that when wet garbage is dumped here and there upon the burning garbage, the fire is suddenly and partially extinguished below. A very irregular burning is caused thereby which it is necessary to improve by the addition of coal. It also requires more skillful stoking and spreading of the heterogeneous material over the large horizontal grate and a more difficult operation in removing the clinkers, than in a furnace with a sloping chute and a grate of much smaller area, on which the material is gradually brought from a moist state to one of great heat, resembling a self-feeding coal furnace.

The amount of garbage burned in each English cell will depend upon its composition and moisture. With proper drying it is usual in Europe to burn 5 to 7 tons per day per cell of 25 square feet of grate area. In the Berlin Experiment Station something less than 6 tons were burned, and owing to the small amount of combustible material in the Berlin garbage it was necessary to add some coal during certain seasons.

Considering the furnaces operated in your city, in the light of the above remarks, the nature of their defects seems to me apparent. The grates of both combustion and drying chambers are horizontal, so that the garbage stays where it drops, and can only be moved forward and spread with some difficulty by the aid of large heavy rakes. The garbage when dumped into the drying chamber is formed into a dense heavy pile, only the upper portion of which is usually raked down upon the combustion grates, leaving the lower portion undisturbed and unburned often until the last of the garbage is consumed at night. This raking down of the upper portion does not insure us that the garbage will be completely burned. Even pulling it down upon the coal fire in front does not do this, unless much more time and skill are used than was observed during our examination.

The amount of garbage burned in Trenton per equivalent of English cell area (see Table II) is as much as about 14 tons, considering only the coal grate surface in the combustion chamber, while in Europe the quantity ranges from six to seven tons. It must be realized, however, that in Trenton much burning takes place in the first or dry chamber. All of the highly combustible materials, as paper, wood, straw and the like, are there consumed and should not be credited to the second or combustion chamber. Although in Trenton, to aid combustion, about 120 pounds of coal are used per ton of garbage, in Europe the unused coal in the ashes of the mixed garbage amounts, roughly speaking, to the same quantity.

The analysis in Table I indicates that, leaving out the ashes with its unburned coal, the net burning quality of European and American garbage is not very different. This evidence, although it is meager, indicates that you cannot maintain a higher rate of combustion per square foot of grate area than is maintained in the furnaces abroad. Independently of the material burned over the grate of the drying chamber, which I think we might estimate as being at least one-fourth of the total amount, we still have a greater amount of garbage proportionally per square foot of grate surface passing through the combustion chamber than is found to be practicable in the best furnaces abroad. From this reasoning we may infer that the combustion in Trenton is not as thorough as in England, and such inference seems to agree with the facts as found. Remedies for this defect of insufficient combustion in the furnace can be obtained: 1. By increasing the number of furnaces. 2. By running the crematory for twenty-four hours. 3. By improving the burning capacity of the furnace.

To increase the number of furnaces is a matter that will need attention in any event at no distant day. By building another furnace at once, the present overcharge could be relieved. Whether an additional furnace had best be built at the present site or in another part of the city, where it might decrease the length of haul for collection for some districts, while increasing the unit cost of labor for attendance, I did not ascertain. Should it be found impracticable to build another furnace at present, it is entirely practicable to run the present crematory for twenty-four hours, by using two or probably three shifts.

Continuous operation has merits, in a more uniform service and in a saving of the losses of heat due to cooling and to the starting of fires every day. At present you are frequently obliged to run during a portion of the night, and the additional cost of running continuously would not be proportionately greater. Continuous operation requires storage of the garbage for use during the hours when no collections are made. Should all garbage be collected in 12 hours and burned at a rate to consume it in 24 hours, storage must be provided for one-half a day's supply. This at present would be about 15 tons, requiring about 25 cubic yards of storage. If piled 2 feet high this requires a space less than 20 feet square, for which there is ample room.

Referring to what has been said regarding the preliminary draining of the garbage and what will yet be said regarding the feeding to the fires, this storage on the feeding floor is an advantage to be recommended to you also for day service, whenever the state of the fires and an unfavorable previous charge makes temporary storage of some of the garbage necessary in order to obtain better combustion. The temporary storage of this material for a few hours cannot cause any nuisance if it is freshly collected. Such storage is customary in Europe under similar conditions.

While the continuous operation of the furnaces can relieve some of the present difficulties, the third mentioned remedy, namely, the improvement of certain parts of the furnaces, should be likewise recommended. An improvement which I believe to be of much practical value in securing complete combustion without excessive loss of heat, is the introduction of the sloping grate, and of a drying chamber having a floor sloping towards this grate at a different angle to feed, if not automatically, yet with only slight aid from the stoker. By this means the garbage passes gradually from its natural state to that of complete combustion, and the difficulties of stoking are reduced to a minimum. The hottest fire will be near the front of the furnace, and here the fumes get their most effective burning.

The gases should therefore leave the furnace near the front. They should pass to the rear outside, but closely to the walls of the drying chamber, and in such a manner that these are heated as much as practicable, and thus help the drying process from the bottom, sides and rear of the chamber, as direct radiation from the hottest fire helps it in front.

Should the garbage be well drained on the feeding floor, the drying chamber would need no grate nor evaporating pan.

Regarding the introduction of forced draft by blowers forcing air under the grates, it may be said that the advantage of this assistance is recognized in Europe and utilized in the best furnaces. I have no hesitation in expressing the belief that an improvement in the design and operation of your furnaces, with a greater air pressure below the grate, could enable steam to be made in sufficient quantity to operate such blowers, but also, as may be inferred from what has been said above, accomplish the burning with better effect as regards the escape of unburned particles than the aspiration from a more rapid chimney draft, drawing up the fumes from the upper surface of a mass of burning garbage.

Under the present heading it yet remains to speak of the auxiliary fires burning between the furnace and the chimney. Without question such fires are needed at times when for one reason or another it is advisable separately to cremate the fumes coming from the furnace before they ascend the chimney. In your case this may always be required, because the location of the crematory is near the built-up parts of the city, and because the difficulty in training men to operate such a plant properly always points to the wisdom of having a safeguard against slight imperfections of manipulation. Such auxiliary fires must, however, also be carefully run to secure the object for which they are kept burning, and at any time proof of this should be readily obtainable by inspection.

3. The Operation of the Furnace.—Almost, if not equally as important as the proper design of a furnace, is its skillful operation, and too little attention has usually been given in our country to this feature of garbage destruction. A little indifference or carelessness even with the best furnace can result in incomplete combustion, with the resulting annoyance above described. It is a simple matter to burn a homogeneous material, such as coal or wood, but to operate a furnace with probably the most complex mass of matter apt to be found in a modern community, is difficult and also serious from the deleterious effects resulting from failures. The employment of specially trained firemen having good judgment, attentive and faithful, seems to determine the success or failure of the undertaking.

Good judgment with regard to the conditions and time of firing and feeding of garbage and with regard to the selection of material for succeeding charges so as to maintain the necessary heat, close attention to all of the dampers for regulating the drafts either when feeding, stoking or cleaning, scrupulous care in seeing that no unburned particles are removed with the ashes, are all simple matters, though when they fail even singly they may give imperfect results, and failing together they may be disastrous.

When the garbage is delivered at the crematory too rapidly, or not in the best order for firing, as already mentioned, it should be stored. The storage may be in the carts themselves, or on the floor near the feeding holes, as done without annoyance in nearly all crematories abroad. When a load of paper, wood and rubbish arrives, it should not, as was observed on one of our visits, be charged on top of a load of fresh garbage, but be dumped to one side and fed at a time when its fuel value for the moist material will be more effective. This heat value of the dry rubbish is quite appreciable, and in one instance was estimated roughly at one-third the value of a ton of coal, without being utilized for the burning of any fresh kitchen garbage.

The temporary storage of the garbage on the floor over the furnaces, for a better mixing and drying of the same, requires suitable gutters to be formed on it which will collect the water and carry it to the sewer.

Careful attention must also be given to the auxiliary fires, so that they burn briskly at times when the conditions for the escape of odorous fumes from the furnace are most favorable.

All ash pits, flues, dust chambers and other parts of the furnace must be frequently inspected and cleaned, since any deposits may contract the sectional area of the flue and thereby modify the normal draft through them.

Resume and Recommendations.—It now remains briefly to summarize the foregoing into a statement of the annoyances you are experiencing, with recommendations of the most efficient practical means of removing them. Notwithstanding the existing defects and the criticisms which it has been necessary to make, the Trenton furnaces belong to the better class of such plants in our country. The troubles and nuisances with which you are now contending are also more or less common elsewhere.

The chief reason for this fact appears to be the insufficient attention that has been given the subject by those best able to do so. Sufficient inquiries have not been made into all the various causes of the specific troubles, so as to correct each and all of them in an intelligent manner. In many quarters there appears to be even a lack of appreciation of the real difficulties involved in the problem, both as regards construction and operation. Especially as to the latter there is a disposition to undervalue the necessity of having operators with a good practical knowledge of firing such a complex material as garbage, so as to obtain complete combustion, of the effects and interaction of drafts in furnaces operated separately, but leading into the same main flue, and of the means for settling the dust which rises with the fumes. As soon as these difficulties are more generally appreciated, their proper solutions will no doubt soon follow.

The character of the Trenton garbage collection is at present fairly satisfactory. The best practice in this climate regarding the receptacles at the house suggests galvanized iron buckets with cover. These become less foul than if made of wood, and the covers prevent the scattering of the material by animals or wind and the dissemination of filth by flies. The collection in well-constructed metal carts such as you have and also the frequency of your collections are quite satisfactory. It may be suggested, however, that provision for thorough cleaning of the carts after dumping would be a still further improvement. To obviate the escape of odors from ashes that have not been completely burned, it is necessary to have furnaces that will economically burn the garbage, and also very attentive as well as skillful firemen, trained and experienced in this special kind of work.

To obviate the nuisances of dust escaping at the stack, either from well burned or unburned garbage, it is necessary after securing perfect combustion, to introduce a dust-settling chamber of proper size between the furnaces and the stack, containing baffles and properly placed inlets and outlets. The screens now in the chimney, although useful as a safeguard against accidental emissions of light but large matter, are insufficient to retain all of the matter now escaping from the furnaces.

To reduce further the possibility of unburned particles escaping through the stack, it is important to place dampers in the flues leading from each furnace, as well as in the chimney, so as to afford control of the drafts at all points where and when it is needed. Skillful observation at every moment of the condition and character of the garbage, and faithful attendance in operating the dampers to maintain an effective velocity of the gases, which at the same time does not carry the dust, are necessary to obtain success.

The prevention of odors due to unburned gases escaping from the stack depends upon the character of the garbage, the sufficient capacity of the furnace, its design and the operation of the plant.

The garbage now delivered, when properly drained and carefully burned in a well designed furnace, is readily combustible, and should not require the addition of as much coal as now used; and at some seasons, except to start fires and otherwise on rare occasions, perhaps no coal may be required.

We find that the furnaces are not sufficient in size to effect a complete destruction of the material during the hours of the day when the crematory is operated. Continuous firing for twenty-four hours can relieve this deficiency. To this end it would be necessary to store the material for a part of the day, and this could not be objectionable in any way.

To secure a complete combustion of the garbage more economically than at present, the design of the furnaces should be somewhat altered. The horizontal grates are not the most suitable for the material, which must first be dried and then with difficulty pulled from one position to another for burning. A sloping grate for burning and a sloping floor for the drying chamber, from which the material can be gradually and almost automatically moved from the feed hole to the hottest fire, permit of a better utilization of the heat and reduce the difficulties of stoking.

The gases should leave the furnace from a point above the hottest fire, and be utilized to heat the walls of the drying chamber so as to assist in the proper preparation of the garbage for burning. Forced draft under the grate will also be of great advantage in aiding combustion.''

Auxiliary fires for burning the fumes before they rise into the chimney are a wise addition to your crematory, and should be retained as a safeguard on account of nearness to the inhabited parts of the town.

The Convention of the New England Water-Works Association.

The twenty-first annual convention of the New England Water Works Association was held this week at the Hotel Brunswick, Boston. The opening session was called to order Wednesday morning by President Frank E. Merrill, and the address of welcome was made by ex-Mayor J. O. Hall, of Quincy, Mass. The following applicants were then elected members of the Association. Active members: H. V. Macksey, in charge of meters, fire pipes, etc., Boston water works; Edward T. Waters, biologist, Metropolitan Water and Sewerage Board, Boston; Fred J. Taylor, chief engineer and superintendent of water works at Westboro Insane Hospital, Westboro, Mass.; William E. Johnson, engineer for Board of Water Commissioners, Hartford, Conn.; John F. Miller, with Pennsylvania Water Company, Edgewood, Pa.; John W. Hill, chief engineer, Bureau of Water Filtration, Philadelphia, and J. A. Canals, City Engineer of San Juan, Porto Rico. Associate members: John M. Holmes, Philadelphia, Pa.; Stilwell-Bierce & Smith-Vaile Company, 73 Oliver street, Boston, Jenkins Brothers, 17 Pearl street, Boston and Mr. Alphonse Fteley, formerly chief engineer of the Croton Aqueduct Commission, was elected to honorary membership in the Association.

At the afternoon session, Wednesday, a paper entitled "Duties of Municipalities Regarding Water Supply," was read by Hon. J. O. Hall, of Quincy, Mass. This was followed by the presentation of the report of the committee on "Standard Specifications of Cast Iron Pipe," by the chairman, Mr. Freeman C. Coffin. This report is reviewed elsewhere in this issue. Printed copies of the report, together with the proposed specifications, were distributed among those present and an earnest request was made by the president for a full discussion of the subject. After reading the report Mr. Coffin briefly explained wherein it differed from the preliminary one presented at the meeting in December, 1901. Such changes as had been made were adopted only after a thorough investigation, both by the Association's committee and one representing the pipe manufacturers, and after receiving and considering many written and oral suggestions from members and others interested. While these specifications did not embody every point which might seem desirable by engineers, yet Mr. Coffin believed that, for general practice, they would fill all present requirements, and the committee felt no hesitancy in recommending their adoption.

In the discussion which followed the presentation of this report, Mr. Leonard Metcalf stated that he saw little to criticize in it. He thought the committee deserved great credit for its patient and painstaking work and he hoped the result would be far-reaching. As to the question of adopting these specifications he was in doubt as to the wisdom of taking final action at this meeting, and asked if it would not be well to wait until it was known whether other associations would follow suit.

In reply to this question Mr. Coffin stated that the committee felt that it had done its work and that little could be gained by delay. It was not likely, he thought, that other associations would take the initiative in this matter. On the other hand information had reached the committee to the effect that the American Water Works Association had intimated, through its committee appointed to consider the subject, that, should action be taken by this society at this time, similar specifications would be adopted by it.

Mr. Morris Knowles, of Pittsburg, Pa., asked if it was desirable to have so many classifications. There seemed to be a difference of opinion, he said, between the committee and the manufacturers, the latter believing it would be an advantage to have fewer sizes. It was very frequently the case that lighter pipe cost more to manufacture than heavier pipe of the same diameter where in many instances there would otherwise be no particular choice between the two. In reply to this question Mr. Coffin stated that he knew of members of the New England Water Works Association who were using light weight pipe such as had been provided for in these specifications. It was known that the cost of this pipe was greater than that of heavier weight. It was not for him to discuss the relative merits of either, but, since the lighter weights were being used by members of the association, the committee had thought it wise to make provision for them in the specifications.

Mr. G. H. Benzenberg, of Milwaukee, Wis., continued the discussion by stating that he felt that the requirements had not been made rigid enough and particularly so regarding the matter of coating. He thought the time would come when a galvanized coating would be generally used for water pipe. It was true that the cost of such coating would be greater than that used at the present time, but the efficiency and durability of the pipe would also be greatly enhanced. Experience has shown that, if requirements were set high, the contractors would meet them.

Mr. W. C. Hawley, of Wilkinsburg, Pa., stated that he desired to emphasize the importance of the subject of coating. He thought that this matter should receive greater attention than it had hitherto. The question of enforcement was one also which needed attention. It would make no difference how good a set of specifications could be devised, the contractor would pay little attention to them unless an inspector was constantly on hand to enforce them.

Mr. Dexter Brackett, a member of the Committee, stated that it would be impossible to carry out all that engineers might desire. He was of the opinion that the requirements in the committee's specifications can be enforced. Personally he would like to see a better coating for water pipe. There was no reason why any city could not improve upon these specifications, if they so desired. For general practice, Mr. Brackett thought that the Committee had gone as far as it could for the present time.

On motion of Mr. E. H. Gowing, the report was then adopted and the specifications in it made the standard of the association.

At the Wednesday evening session an illustrated talk on "Recent Construction on the Metropolitan Water Works" was given by Mr. Frederick P. Stearns, chief engineer of the Metropolitan Water and Sewerage Board of Boston. A paper on "The Water Supply of Nashua, N. H.," was then presented by Mr. Horace G. Holden, superintendent of water works of that city.

A paper entitled "A New Turbidimeter," by Charles Anthony, Jr., Hereford, England, was read by Mr. Charles W. Sherman at the opening of the Thursday morning session, and discussed by Mr. Sherman and Mr. Allen Hazen. It was followed by a paper entitled "The Removal of Color and Odor from Water," by Mr. H. W. Clark, chemist of the Massachusetts State Board of Health, Boston.

The report of the Committee on Apportionment of Charges for Private Fire Protection, and the Means of Controlling the Supply Thereto was then called for. This committee consisted of Byron I. Cook, Edward V. French, J. C. Hammond, Jr., Charles K. Walker, John C. Chase, F. H. Crandall and Henry A. Fiske. This committee having failed to agree, three separate reports were presented, one by Messrs. Crandall, Walker and Hammond; another by Messrs. French, Fiske and Cook, and a third by Mr. Chase. Each member of the committee then stated his reasons for taking the stand he did, and the matter was also discussed by other members of the association. The motion to accept these reports and to have them printed as part of the proceedings of the convention was carried. At the afternoon session the subject of these reports was again called up. Mr. Crandall stated that the committee had labored under great difficulty from the fact that little expression of opinion had been made by members of the association. He thought it desirable at this time that some action should be taken which would show what that sentiment was. A motion to accept the report presented by Messrs. Crandall, Walker and Hammond was then made, but was afterwards laid upon the table. Upon motion of Mr. Frank C. Kimball, superintendent of water works, Knoxville, Tenn., it was voted to appoint a new committee of three representing both public and private companies to confer with similar committees of the American Water Works Association, the Central States Water Works Association, and the various associations of fire underwriters, with the view of considering adequate means for the payment and control of water for private fire protection. The president stated that this committee would be appointed before the adjournment of this meeting.

A paper entitled "The Physical Properties of Water" was next read by Mr. Allen Hazen. At the conclusion of this paper Mr. Hazen described a device for measuring the turbidity of water. The report of the Committee on "Uniform Statistics" was next presented and was adopted in full by the Association. At the Thursday evening session Mr. Desmond FitzGerald, engineer, Sudbury Department Metropolitan Water Works, Boston, gave an account of "What an Engineer Saw in Venice." This was accompanied by lantern slides. An historical address entitled "Twenty Years After—A Retrospect," was next read by Mr. R. C. P. Coggeshall, superintendent of water works, of New Bedford, Mass. An excursion to the works of the Metropolitan Water Commission at Clinton, Mass., was made by the members of the association on Friday.

Personal Notes.

Mr. William C. Ogden has been elected civil engineer of Dover, N. H.

Mr. O. M. Rankin has tendered his resignation as city engineer of Ballard, Wash.

Mr. George W. Shock has been elected superintendent of the South Bend, Ind., water works.

Mr. E. E. Batton has been appointed chief draftsman in the civil engineer's office of the Detroit water board.

Mr. C. C. Radabaugh has resigned his position as superintendent of the Alexandria, La., electric light and water works plant.

Mr. George G. Earl, M. Am. Soc. C. E., has been re-elected general superintendent of the Sewerage and Water Board of New Orleans.

Mr. E. P. Mobley, roadmaster of the eastern half of the Eastern Division of the Chicago Great Western Railway, has been appointed division engineer of the Southwest Division with headquarters at Des Moines, Ia., to succeed Mr. W. B. Causey, resigned.

Mr. Freeland Howe, Jr., has resigned his position as assistant bacteriologist at the testing station of the Spring Garden Water Works, Philadelphia, to accept an appointment as chemist and bacteriologist in the laboratories of the filtration works at Harrisburg, Pa.

Mr. Wm. C. Whitner has resigned the duties of chief engineer of the Catawba Power Co., Rock Hill, S. C., to become chief engineer of the power and lighting department of the Virginia Passenger & Power Co., of Richmond. This corporation is an amalgamation of the Richmond Passenger & Power Co., the Richmond Traction Co., the Virginia Electric Railway & Development Co., and the Southside Railway & Development Co. It owns valuable water powers in Richmond and Petersburg, which will be developed as rapidly as possible.

A Leaky Sewer of 12-inch vitrified pipe in the town of Clinton, Mass., is stated by the Metropolitan Water and Sewerage Board to have furnished 200,000 gallons of water per day to the sewage filtration plant before any house connections at all had been made.

The Extension of the Septic Tank System at Exeter, Eng., is designed to serve a population of 47,000, the maximum flow of sewage and storm water provided for being 2,500,000 imperial gallons per day. There are three grit chambers, six septic tanks and twelve bacterial contact filters, all built in concrete. The main outfall sewer discharges into the grit chambers, which are 18x6 feet and 3 feet deep. From these the sewage is delivered to each of the tanks through four submerged inlets. Each tank is 180x36 feet, and 8 feet deep below the springing of the concrete covering arches. The effluent passes off through slotted pipes laid horizontally across the ends of the tanks 3½ feet below the springing. It was only after 5 years' continuous use that it became necessary to remove any deposit from the experimental tank erected in 1896, so it is not expected that the new tanks will require to be cleaned of sludge except at long intervals. Each filter is about 1,000 square yards in extent, the total area being about 2½ acres. They are filled with ½-inch furnace clinker to a depth of 3½ feet. The tank effluent will be distributed, according to "The Surveyor," over each filter in turn by 11 lines of stoneware channels laid on top of the filtering material. The final effluent will be collected by agricultural drain pipes laid on the floor. These beds are arranged in groups of four, each group surrounding a central gear chamber. Two of the groups will ordinarily form the working set, and the tank effluent will be automatically delivered to each filter in turn. The discharge valve will meanwhile be closed and the tank effluent will remain in the filter about an hour and a half. The filling and emptying of the filters is effected automatically by means of the alternating gears, consisting of levers from which the admission and discharge valves are suspended. The discharge valve lever has an actuating bucket at one end and a counter-weight at the other, and the admission valve is opened by a weighted float. The work has been carried out under the direction of the inventor of the system, Mr. Donald Cameron.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xviii and xxvii.

WATER.

Findlay, O.—Bids will be received by the Water Wks. Trus. until Sept. 17 for furnishing material and constructing a conduit to supply water for the city water works. Approximate quantities: 4,325 tons of cast-iron pipe, 15 tons of special castings, 9,000 ft. of well connections, about 11 miles of 24-in. vitrified pipe, 24, 20 and 8-in. gate valves, etc. Wm. Demland, Secy.

Water bonds amounting to $150,000 are stated to have been sold.

De Smet, S. D.—The Mayor writes that bids will be received until Oct. 1 for constructing a water works and an electric light plant. Estimated cost, $20,000.

Chamberlain, S. D.—See "Government Work."

Chester, Pa.—Geo. Hodkinson, of Chicago, Ill., is stated to have secured the contract for a filter plant for the New Chester Water Co., to be erected on Harrisons Hill. Wm. G. Chadwick, Supt.

Prosper, Tex.—The Prosper Water Works Co. has been incorporated; capital $4,000. Incorporators: W. C. Naugle, W. R. Mathers and A. T. Bryant.

Tonawanda, N. Y.—The citizens are stated to have voted Sept. 4 to issue $30,000 bonds to improve the water works.

New Castle, Del.—Prominent citizens and property holders are reported to be agitating a movement for new water works. The intention is to supply the city with pure water taken from a series of artesian wells.

Atlanta, Ga.—The Bd. of Water Comrs. on Sept. 5 decided to ask the City Council to authorize a bond issue of $400,000 with which to make improvements at the water works, to consist of a new reservoir, a 20,000,000-gallon pump for the river station, a 36-in. main connecting the river station and the new reservoir, and also new filters.

Burlington, Ia.—Local press reports state that the Citizens Water Co. on Sept. 2 purchased the plant of the Burlington Water Co. The Citizens Water Co. was incorporated Aug. 12 by W. W. Baldwin, Edward Hagemann and others, to acquire, operate, improve and extend the existing system of water works in Burlington, by and with the consent of the city and under a contract with the city.

Newark, Ark.—E. H. Williamson writes that there is talk of constructing water works, at a cost of about $5,000.

Arlington, N. J.—A press report states that an ordinance has been introduced in the Boro. Council of North Arlington, granting the Union & Bergen Water Co. a franchise to run water pipes through North Arlington

Price, Utah.—Reuben C. Miller, of the Town Council, is reported to be figuring with an engineer on the cost of constructing water works.

Marseilles, Ill.—The Marseilles Water & Light Co., Marseilles, is reported incorporated with a capital of $10,000, to operate a system of water works. Incorporators: Mark A. N. Earle and Wm. S. Hammond, Jr.

Minden, La.—It is reported that the establishment of water works is under consideration.

Lonaconing, Md.—The Midland-Elk Lick Water Co. is stated to have petitioned the Council for a franchise to pipe the streets and furnish water.

Meadville, Pa.—W. A. Doane, City Engr., writes that $1,000 has been appropriated by Council for further tests of wells for new supply.

Carthage, S. D.—The Town Bd. is reported to be investigating the cost of water works.

Centralia, Ill.—The City Council is stated to have passed an ordinance authorizing an extension of the water mains into the Parkside addition.

Jamaica, L. I., N. Y.—The Bd. of Estimate is stated to have decided Sept. 5 to appropriate $40,000 for construction of distributing main in the 1st Ward, Queens Boro.

Manzanola, Colo.—The Artesian Water Co. is stated to have petitioned the Council for a franchise to furnish the city with water.

Boalsburg, Pa.—The Boalsburg Water Co. has been incorporated; capital, $2,600. Directors: J. M. Wieland, P. S. Ishler and J. A. Fortney, Boalsburg.

Wheeling, W. Va.—Local press reports state that Michael McKinney, Supt. Water Works, estimates the total cost of constructing a new main from the pumping station to the reservoir at $58,028.

Wyandotte, Mich.—See "Power Plants, Gas and Electricity."

Fremont, O.—The Water Works Trustees have decided to advertise for bids for a 100-120-H.-P. air compressor to obtain a supply of 2,000,000 gals. of water per day from a system of wells.

Allentown, Pa.—The Secy. of the Water Comrs. writes that it is proposed to secure a water supply from Schantz's Spring, the work to cost about $200,000. Bids will be asked in about 3 months. G. J. S. Kohler, Pres.; J. Howard Martz, City Engr.

Hawkesbury, Ont.—Denis Doyle, Town Clk., writes that the Montreal Pipe Foundry Co., Montreal, Que., has secured the contract for 750 tons of cast-iron pipe at $38 per ton and special castings $3 per 100 lbs.

Chicopee Falls, Mass.—The Committee on Fairview Water Supply has reported favorably to Bd. of Aldermen for an appropriation of $35,000 to be met by bond issue if passed by 1903 Legislature.

Yellow Springs, O.—The Ohio Water Delivery & Irrigation Society has been formed here, to promote the preservation of water and to encourage its delivery to farms and villages by pumping stations and by pipe lines along the highways. John Bryan, Pres., Yellow Springs.

Galveston, Tex.—At a meeting of the City Comrs. Sept. 2, C. G. Wells, City Engr., and A. S. Drewry, Supt. Water Wks., submitted estimates of the cost of an additional water main pipeline across the bay. A 20-in. pipe would cost $83,000; 24-in. pipe, $91,000, and 30-in. pipe $106,000. It was reported back for further estimate of 8 and 12-in. pipes and cost of a pumping station to be erected at Virginia Point.

Woodward, Okla. Ter.—A charter is reported to have been issued to the Woodward Water & Milling Co., of Woodward, for a term of 20 years, to sink wells, for water, salt, coal, gas, oil or any other mineral in or near Woodward; capital, $30,000. B. W. Key, J. W. Magee and John Garvey, all of Woodward, are reported interested.

Questa, N. M.—A press report states that Duane Wheeler has been engaged to survey an irrigation canal for the Taos County Irrigation & Improvement Co., at Questa.

Portland, Ore.—Local press reports state that D. D. Clarke, Engr. Water Com., estimates the cost of lowering submerged pipe lines, total length to be lowered 1,620 ft. 28-in. pipe, $17,200, and 24-in. pipe $15,500.

Waco, Tex.—The City Council is stated to have passed a resolution authorizing the Mayor to appoint a commission to study the water question, to determine the cost of building an independent system and to ascertain what the present system, owned by private parties, can be bought for. The resolution also authorizes the employment of John W. Maxcy as engineer to advise the Bd. of Water Comrs. as to the construction or purchase of water works.

Pittsburg, Pa.—Local press reports state that Director J. Guy McCandless has sent to Common Council an estimate of the cost of the proposed sand filtration plant; the estimated cost is $3,719,000. This does not include the cost of covering the filter beds, which it is estimated will cost about $800,000 more.

Thomson, Ga.—Ira E. Farmer, Mayor, writes that the town is now engaged in boring two deep wells to be used as a source supply. If the well is a success they will be in the market for pumping machinery, and also for the construction of a system of water works. Engineer not yet named. The cost of wells and water works will approximate $15,000.

Marshall, Tex.—The citizens are stated to have voted Sept. 4 to issue $25,000 bonds for improving the water works.

Minneapolis, Minn.—Water bonds amounting to $250,000 were sold Sept. 6.

Black River, N. Y.—Eaton & Brownell, of Carthage, are stated to have been selected to make a survey with specifications and estimates, for water works and a sewerage system.

Berkley, Va.—Geo. Hornung, Gen. Mgr. of the Norfolk County Water Works, is reported to be making surveys across the Southern branch of the Elizabeth River to lay a water main to supply Berkley with Lake Kilby water.

Washington, D. C.—Bids were opened Sept. 6 by the Comrs. D. C., for 30, 36 and 48-in. cast iron pipe and specials, as follows: *a*, 6,000 long tons straight pipe; *b*, 135 tons of specials: U. S. Cast Iron Pipe & Fdy. Co., *a* $32.70, *b* $117, total $211,995; Camden Iron Wks., *a* $35.90, *b* $78, total $225,930.

Cle Elum, Wash.—The citizens are stated to have voted to issue $9,500 bonds for the construction of water works.

Chanceford, Pa.—A charter is stated to have been granted to the Hillside Water Co. for the storage and transportation of water and water power for commercial and manufacturing purposes in Lower Chanceford, office to be at Lancaster. Directors: Jacob Hill Bryne, W. F. Jack, and others, all of Lancaster.

Platteville, Colo.—The State Land Bd. is stated to have granted C. L. Walker a reservoir site at Platteville. The reservoir is to cover 14⅓ acres and is to be built for irrigation purposes.

Middleport, N. Y.—The Village Trus. are stated to have granted F. A. Dudley's Co. a perpetual franchise for water works, the company agreeing to furnish five taps free for fire purposes.

Philadelphia, Pa.—Bids are wanted Sept. 17 (readvertisement) for constructing Lardner's Point Pumping Station No. 2. Wm. C. Haddock, Dir. Pub. Wks., Bureau of Filtration.

Local press reports state that Wm. C. Haddock, Dir. of Pub. Wks., is to receive bids until Sept. 18 for the high service pumping station to be erected at Delaware Ave. and Race St.

Stoneboro, Pa.—Bids are wanted Sept. 22 for constructing a gravity water works system, to consist of a 224,000,000-gal. concrete reservoir, 12,000 ft. of 6-in. and 2,000 ft. of 4-in. cast iron pipe, 75 taps with boxes and necessary valves and Ts. Frank McSweeney, Boro. Treas.

Beaumont, Tex.—It is reported that the Water Works Co. of Beaumont will probably extend its lines to the Big Sand River.

Monticello, Minn.—J. L. White writes that the National Construction Co., of South Bend, Ind., has secured the contract for an air lift water works system, for $10,000.

Stephenville, Tex.—The citizens are stated to have voted to issue $10,000 water works bonds.

Gas, Kan.—This city has voted $30,000 for water works, and has employed Burns & McDonnell, of Kansas City, Mo., to prepare plans and specifications for same.

Whittier, Cal.—A press report states that N. W. Stowell, of Los Angeles, has purchased the East Whittier Land & Water Company's pumping plant, 14 miles of ditches and 126 acres of water bearing land, and will expend about $40,000 in improving and extending the system.

Lincoln, Ill.—The Lincoln Water & Light Co. has been incorporated, with a capital of $250,000, to operate a light and water plant. Incorporators: Ralph Blaisdell, P. B. Warren and Geo. H. Withrow.

Albuquerque, N. M.—It is stated that the Socorro Investment & Promotion Assoc. will petition the City Council for a franchise to lay irrigation pipes in this city for the purpose of conveying water from its pumping plants for irrigation purposes, and also for an electric light and power plant. The company will also pump water to the east side of the Rio Grande to irrigate that section.

Corvallis, Ore.—Sidney Smith, of Portland, is stated to have petitioned for a water works franchise. He proposes to pipe water from the mountains for a distance of 15 miles, if the City Council will grant him a franchise.

Milwaukee, Wis.—Bids were opened Sept. 5 as follows for 8-million-gal. pumping engine: Holly Mfg. Co., $45,000; Barr Pumping Eng. Co., $65,000; Allis-Chalmers Co., of Chicago, Ill., plan A, $29,400; plan B, which was accepted Sept. 9, $31,700.

Baldwins, L. I.—The following bids were opened Sept. 11 for a pumping plant at Millburn Engine House, Baldwins, L. I.: Henry R. Worthington, $51,000 and $59,000; Snow Steam Pump Wks., $50,000. Bids were also received as follows for two boilers: Jas. Reilly Repair & Supply Co., $12,376; Edwin Burhorn, $11,400; J. Edw. Ogden Co., $11,800.

Grossdale, Ill.—Bids will be received by the Bd. of Local Improv. until Sept. 16 for furnishing and laying 43,000 lin. ft. of 6-in. and 8,000 lin. ft. of 4-in. mains, 121 double nozzle hydrants, and 42 valves and valve boxes. W. B. Ewing, C. E., 1003 Chamber of Commerce, Chicago.

Baraboo, Wis.—Bids will be received by the Health & Water Com. until Sept. 25 for furnishing machinery and constructing a brick power house for the new water supply; also for drilling two 16-in. wells, 400 ft. deep. W. G. Kirchoffer, Engr. in charge.

North Milwaukee, Wis.—Bids will be received by the Village Bd. until Sept. 19 for furnishing 466 tons of cast-iron water pipe, as follows: 313 tons of 8-in., 122 tons of 6-in. and 31 tons of 4-in. W. E. Chase, Village Clk.

Cleveland, O.—Bids are wanted Oct. 3 for construction, delivery and erection in the boiler house at Kirtland St. Pumping Station, of 6 water-tube boilers equipped with superheaters, chain-gate mechanical stokers, brickwork and their appurtenances. Chas. P. Salen, Dir. of Pub. Wks.

Gibbon, Minn.—Bids will be received by E. F. Maetzold, Village Recorder, until Sept. 26 for a 6 H.-P. gasoline pumping engine.

Ballard, Wash.—The Pacific Coast Pipe Co., of Ballard, is stated to have secured the contract for laying the water mains for about $10,000.

Bennett, Ia.—C. H. Meredith, of Cedar Rapids, is reported to be preparing plans for water works.

Litchfield, Ill.—Henry J. Croft, City Clk., writes that it is proposed to extend the water mains.

Pittsburg, Pa.—Bids will be received by the Co. Comrs. until Sept. 19 for erecting a mechanical filtration plant in the County Jail. W. E. Thompson, Co. Compt.

SEWERAGE AND SEWAGE DISPOSAL.

Wooster, O.—Bids will be received by J. B. Minier, City Clk., until Sept. 20 for constructing a sewer in Beall Ave., including necessary manholes, catchbasins, etc.

New Orleans, La.—Geo. G. Earl, Gen. Supt. Sewerage and Water Bd., writes that all bids opened Aug. 12 for sewers were rejected Sept. 3.

Thompsonville, Conn.—Local press reports state that bids will be received by the Sewer Comrs. until Sept. 20 for constructing a sewer in Elm and North Main Sts., requiring 3,100 ft. of 8-in. pipe.

Des Moines, Ia.—Bids are wanted Sept. 17 for constructing an 18-in. pipe sewer in 2 streets. J. E. Stout, Clk. of Bd.

Muscatine, Ia.—Bids are wanted Sept. 18 for constructing a stone sewer in Oak St. Jas. J. Ryan, City Engr.

Long Island City, N. Y.—Bids will be received until Sept. 18 by Jos. Cassidy, Boro. Pres., for furnishing material and constructing 2,435 lin. ft. of 12, 15 and 18-in. pipe sewer in Hamilton St., and for furnishing material and constructing several small pipe sewers in other streets.

Toledo, O.—Bids are wanted Sept. 22 for constructing 8 and 10-in. circular pipe sewers and 20-in. circular brick sewer with 4-in. shell in portion of several streets. Chas. H. Nauts, City Clk.

Chamberlain, S. D.—See "Government Work."

Glassport, Pa.—D. V. Ault & Co. are stated to have secured the contract for sewers on Bway. and Vermont Aves. for $9,392.

Providence, R. I.—The Bd. of Aldermen is stated to have passed a resolution adding $100,000 to the sewer appropriation. It will be expended on the general system of sewers.

Seneca Falls, N. Y.—The question of constructing sewers and new pavements is under consideration. It is reported that the length of proposed sewerage system would be 14¾ miles, and the estimated cost of construction $68,000.

Youngstown, O.—City Engr. F. M. Lillie is reported to be preparing plans for the Oak St. sewerage system.

Millville, N. J.—A company of Millville capitalists are stated to have petitioned the Council for a franchise to sewer the town.

Peoria, Ill.—The Crescent Stone Co., 117 N. Jefferson Ave., is stated to have secured the contract for constructing the Persimmon St. sewer for $17,000. The Bd. of Local Improv. is stated to have ordered the City Engr. Dept. to prepare an estimate for a sewer in Monson and Sanford's addition.

Hyattsville, Md.—The City Council is reported to be discussing the establishment of a sewerage system.

Glenville, O.—The City Council is stated to have authorized the Clerk to secure bids for a trunk sewer in Doan St.

Pittsburg, Pa.—A charter is reported to have been filed in the Recorder's office of the Monongahela Valley Sewer Co. by Attorney John N. Radcliffe, W. R. Murphy and others, to construct and maintain sewers, culverts, conduits, pipes, with all necessary inlets and appliances for surface and undersurface and sewerage drainage in Jefferson Township, Allegheny County.

St. Paul, Minn.—The following bids are stated to have been opened by the Bd. of Pub. Wks., Sept. 2, for the Dearborn St. and Stryker Ave. sewers: P. Doherty, $14,564; Wm. J. Preston, $13,825, and P. J. Rogers, $15,800.

Virginia, Minn.—There is talk here of constructing a sewerage system.

Qu'Appelle, N. W. Ter.—The citizens are stated to have voted Aug. 29 to construct a sewerage system, to cost $6,000.

Eatontown, N. J.—The Monmouth Sewer Co., of Eatontown, is reported incorporated, with a capital of $100,000, to construct and maintain sewer systems. Incorporators: Jas. Steen, Eatontown, and Ira H. Carpenter, Asbury Park.

Brooklyn, N. Y.—See "Paving and Roadmaking."

Dunmore, Pa.—M. J. Gibbons, of Scranton, is stated to have secured the contract for constructing sewers in Dunmore, for $56,771.

Hartford, Conn.—City Engr. F. L. Ford is reported to have suggested to the Street Comrs. the construction of a trunk sewer for the relief of Franklin Ave., at a cost of about $50,000.

Milwaukee, Wis.—See "Bridges."

South Bend, Ind.—O. A. Garner, of Knox, Engr. of the Reclamation Co., of Knox, writes that it is proposed to construct a drainage canal about 17 miles in length to reclaim the Kankakee marsh; probable cost of work, $95,000.

Waukegan, Ill.—The City Council is stated to have passed an ordinance providing for a sewerage system in the south side, to cost $30,000.

Portland, Ore.—Local press reports state that the City Engr. has about completed surveys for the Cook Ave. sewer system in Albina District.

Elyria, Colo.—The Town Council of Elyria is stated to have appointed a committee to confer with the Globeville Town Council regarding the extension of the Delgany St. sewer. The sewer empties into the Platte between the two towns, and citizens of both places are endeavoring to have it extended beyond the town limits.

Warsaw, Ky.—E. F. Layman is stated to have been selected by the Town Bd. to make an extended survey providing for its topographical reconstruction and improvement. The survey contemplates a complete drainage and sewerage system, paved streets and sidewalks.

Vailsburg, N. J.—The Council is stated to have decided to establish a local sewer system in the borough to connect with the joint trunk sewer.

Lowell, Mass.—The City Council on Sept. 2 passed an ordinance providing for an additional appropriation of $38,000 for sewers.

Wyandotte, Mich.—See "Power Plants, Gas and Electricity."

Brooklyn, N. Y.—In regard to the proposed sewer from 92d St. and N. Y. Bay to 11th Ave. in addition to the item which appeared in this column last week, Ch. Engr. H. R. Asserson, of the Dept. of Sewers, further states that as bids will soon be asked, prospective bidders are advised to post themselves as soon as possible on the material which will be encountered at the tunnel level; cost of proposed work is, as stated, $665,000.

Boston, Mass.—The following bids were opened Sept. 4 by the Boston Transit Commission for side walls and sewer in State St.: Lawler Bros., Charlestown, $38,835; Jones & Meehan, Boston, $29,765; Chas. King & Co., Boston, $26,820; Shailer & Dunfee, Boston, $26,420; Patk. McGovern, Roxbury, $25,349; Met. Contg. Co., Boston, $23,557; E. W. Everson & Co., Providence, $22,170; Gow & Foss, Boston, to whom the contract was awarded, $21,235. The detailed tender of the successful bidder includes 2,400 cu. yds. earth excav. and backfilling at $5.25; 500 cu. yds. concrete at $11; 30 cu. yds. brick masonry at $18.

Harrisburg, Pa.—The following bids are reported opened Sept. 3 by Bd. of Pub. Wks. for constructing Paxton Creek sewer: S. M. Neff, 120 Liberty St., N. Y. City, contract awarded, $167,227; Jas. J. Lynch, Harrisburg, $233,404; Chas. Fisher & Wm. H. Lynch, Harrisburg, $272,250; David Peoples, 25th and Callowhill Sts., Phila., $244,984; B. J. Sullivan, 14 So. Broad St., Phila., $279,446.

Henderson, Ky.—Bids are wanted Sept. 16 for constructing 2,600 ft. of 30-in. pipe sewer. Geo. D. Givens, Chmn. Sewer Com.

Montevideo, Uruguay.—Bids will be received until Dec. 15 by the Uruguayan Government at Montevideo for sanitary work in Montevideo Harbor, including the following: A rock tunnel 1,278 metres in length, 3m. 65 in height and 3m. in width; a main collector 1,557 metres 60 by 1,283, 30m. in length, oval profiles 1.80m. and 1m. 70 in height respectively; a secondary collector 2,016m. in length, varying its oval profiles from 1.70m., 1m. 25 and 0 m. 98 in height; auxiliary collectors, affluents, etc. Plans, estimates, etc., can be had in Montevideo by applying to the "Ministerio de Fomento."

Guthrie, Okla. Ter.—T. A. White, City Engr., writes that E. N. Ford has secured the contract for 5 sections of main sewer and 13 laterals, for a total cost of $38,000.

Victoria, Tex.—The City Council is stated to have instructed the Water Works Com. to secure estimates for a sewerage system.

Black River, N. Y.—See "Water."

Franklin, Ky.—The City Council is reported to be considering the construction of a sewerage system.

Mountain Lake Park, Md.—It is proposed to lay about 3 miles of terra cotta sewer pipe this fall. L. A. Rudisill, Secy.

Danville, Ill.—Bids are wanted by the Bd. of Local Improv. until Sept. 18 for constructing a sanitary sewer in a portion of Park St.

Boston, Mass.—Bids will be received until Sept. 17 by Jas. Donovan, Supt. of Streets, for sewerage works in Tower St.

Birmingham, Ala.—Local press reports state that the survey of the Valley Creek branch of the Jefferson County trunk sewer has been completed and the County officials are at work securing right of way. As soon as this is completed the contract will be let. The branch runs from East Lake through Woodlawn, Avondale, North Birmingham, Pratt City and Ensley.

Fresno, Cal.—The Com. appointed to consider the outfall sewer matter, is stated to have reported recommending the construction of a septic tank as the best method of sewage disposal. Thos. Dunn, Chmn. Com.

Lancaster, O.—It is stated that bids are wanted Sept. 18 for constructing sewers in 3 streets. H. T. Meehling, City Clk.

Allentown, Pa.—Bids will be received by the Mayor, Fred E. Lewis, until Sept. 16, for constructing a storm-water sewer in portions of Hamilton St.

Marion, Ind.—It is stated that bids are wanted Sept. 16 for constructing a sanitary sewer in 36th St. C. G. Robbins, City Engr.

Washington, D. C.—A press report states that the Comrs. D. C. have awarded to Bernard J. Sullivan & Bro., of Philadelphia and New York the contract for constructing an 18-ft. sewer under the Capitol grounds, B St., and New Jersey Ave. for $216,000.

St. Paul, Minn.—Bids will be received by the Bd. of Pub. Wks. until Sept. 16 for constructing a sewer in Farrington Ave. Bids will also be received by the same Bd. until Sept. 19 for constructing sewers in portions of Dearborne St. and Stryker Ave. R. L. Gorman, Clk.

New York, N. Y.—The N. Y. Sewer Constn. Co. has been awarded the contract for an outlet sewer bet. 92d and 93d Sts., on the basis of the following bid, opened Sept. 9: 150 ft. of 4-ft. wooden barrel sewer at $13; 1,637 ft. of 4-ft. brick sewer at $13, $10.75 and $12.75; 213 ft. of 3.5x2 1/3-ft. brick sewer at $7.25 and $6.50; 75 ft. of 12-in. pipe culvert at $1.50; 3 receivg. basins with granite head, at $150, etc.; total, $25,555. The other bidders were John A. Hadert, $34,932; Jos. Burns, $33,480; F. V. Smith Contg. Co., $29,206; John J. McQuade, $34,660; Wm. E. Welch, $31,014; Walter J. Ford, $38,153; F. Thilemann, Jr., $27,888; Wm. J. Moore, $30,246.

BRIDGES.

Terre Haute, Ind.—The Co. Council has been petitioned to build the bridge over the Wabash River at Ohio St. so that the old one can be used meanwhile. It is reported that the total cost of the bridge will be $200,000.

Pawnee, Okla. Ter.—Bids will be received by the Bd. of Co. Comrs. until Sept. 22 for constructing 3 bridges across Arkansas River, 1 each at Cleveland, Ralston and Blackburn. G. P. Moore, Co. Clk.

Paxton, Neb.—Bids will be received by the Co. Comrs. at Ogallala until Sept. 18 for repairing a wagon bridge across South Platte River at Paxton. O. Reed, Co. Clk.

Ft. Wayne, Ind.—The Co. Comrs. are reported to have approved the erection of a bridge across St. Marys River at a point where residents of Marion, Pleasant, Adams and Wayne Townships have petitioned for it. The Co. Council must now vote the money.

Leeds, Ala.—It is reported that the Seaboard Air Line will build a bridge over the Cahawba River just above this place. W. W. Gwathmey, Jr., Ch. Engr., Portsmouth, Va.

Peru, Ind.—The Co. Council has appropriated $5,000 to repair bridge across Wabash River at Broad way.

Utica, N. Y.—The matter of bridge construction over the new channel of the Mohawk River at N. Genesee St. and the Miller road is under consideration by this city and the town of Deerfield, and the matter of how the cost is to be divided must be decided soon. P. L. Schultze, City Engr.

Indianapolis, Ind.—The Co. Council is reported to have increased the fund for the College Ave. stone arch bridge over Fall Creek by $5,000, making the total appropriation $80,000, which it is stated will be available after Jan. 1 next.

Muskogee, Ind. Ter.—The City Council is stated to have made some additional stipulations in regard to the proposition of the Colonial Trust Co., of St. Louis, to build a $40,000 wagon bridge across Arkansas River. The Midland Bridge Co., of Kansas City, is also reported to be a close bidder.

South Valley, N. Y.—All bids received Sept. 2 have been rejected by State Supt. of Pub. Wks. Chas. S. Boyd for a bridge over the Alleghany River on the Alleghany Indian reservation in this city, the lowest bid being in excess of money available. New bids will be received Sept. 15.

Atlantic City, N. J.—It is reported that two $5,000 bridges will be required on the line of the proposed turnpike from Atlantic City to Pleasantville.

Shreveport, La.—The City Council is reported to have passed an ordinance providing for a bridge over Cross bayou.

Pittsburg, Pa.—Repairs to the Point bridge over the Monongahela River are being contemplated. J. G. McCandless, Dir. Dept. Pub. Wks.

Batavia, N. Y.—See "Electric Railways."

Washington, D. C.—The War Dept. is reported to have approved, through Chief Clk. Scofield, the appropriation of $65,000 for reconstruction of pier No. 5 of the Aqueduct bridge over the Potomac River at Georgetown.

Appleton, Wis.—A. E. Heldeman, City Clk., writes that O'Keefe & Orbison, of Appleton, have secured the contract for constructing a stone bridge at John St., bids for which were opened Sept. 3, for $34,750.

Phoenixville, Pa.—See "Electric Railways."

Milwaukee, Wis.—It is reported that Pres. A. J. Earling, of the Chicago, Milwaukee & St. Paul R. R., has agreed to give the city right of way for the 27th St. viaduct and a $25,000 bonus in addition.

The Finance Com. of the Common Council has recommended the passage of an ordinance for $150,000 bridge bonds and $100,000 sewerage bonds, the bridge bonds to be devoted to building a bridge to Jones Island.

Pueblo, Colo.—Local press reports state that the contract for the Northern Ave. viaduct has been awarded to the Ericson Const. Co. for $6,967, and $4.50 per yd. for extra cement work.

Lafayette, Ind.—It is reported that a petition has been presented to the Co. Comrs. for a bridge across the Wabash River at Granville.

Seattle, Wash.—City Engr. Thomson is stated to have estimated the cost of a pile bridge and approaches at Railroad Ave. from Broad to University St. at $44,000.

It is reported that the contract for the Latona bridge has been awarded to J. A. Bailey for $49,079.60.

Portland, Ore.—Joseph Buchtel, of the East Side Improvement Assoc., is reported to be in favor of replacing the Grand Ave. bridge over Sullivan's Gulch with a steel truss structure.

New Brunswick, N. J.—A. Atkinson, City Engr., writes that the following bids were opened by the Bd. of Freeholders Sept. 3 for the construction of a bridge over Raritan River connecting Perth Amboy and South Amboy: Sandford & Harris, Hoboken, $146,950 (awarded); F. R. Long Co., Hackensack, $135,000, $142,000, $146,000, $149,000 and $124,000; American Bridge Co., New York, N. Y., $148,000; Berlin Construction Co., East Berlin, Conn., $148,900. The bridge will be 4,082 ft. long and 26 ft. wide.

Hume, N. Y.—See "Paving and Roadmaking."

West Stewartstown, N. H.—It is stated that an iron bridge will be put in to replace the railroad bridge over the Connecticut River, recently burned.

Kansas City, Kan.—City Engr. Stockman, Birmingham, $43,000; Gude & Walker, Atlanta, Ga., $28,900; Miles & Bradt, Atlanta, $28,256; Congress Const. Co., Chicago, $31,893; Fonde Bldg. Co., Mobile, $28,500; A. B. Stannard, N. Y. City, $47,584.

Elmira, N. Y.—Flahire & Krawl, Elmira, were lowest bidders for heating and ventilating apparatus for post office, in amount $4,329, with $660 additional for pipe covering.

Ft. Morgan, Ala.—Bids will be received by L. Cravens, Q. M., until Sept. 17 for sinking an artesian well at this post.

Buffalo, N. Y.—Bids are wanted Sept. 17 for excavating at Ogdensburg Harbor, N. Y. Maj. T. W. Symons, Corps Engrs., U. S. A.

Chamberlain, S. D.—Bids will be received until Sept. 25 by the Comr. of Indian Affairs, Dept. of the Interior, Washington, D. C., for furnishing material and constructing a brick dormitory, with plumbing, acetylene gas piping and steam heat, and extensions to the water and sewer systems at the Chamberlain School, S. D. For further information apply to John Flinn, Supt., Indian School, Chamberlain.

San Francisco, Cal.—Bids will be received until Oct. 11 by Mordecai T. Endicott, Ch. Bureau of Yards & Docks, Navy Dept., Washington, D. C., for constructing 80,000 sq. ft. of asphalt pavement at the Navy Yard, Mare Island, Cal.

Philadelphia, Pa.—Bids are wanted Oct. 11 for constructing a brick and steel building at the Navy Yard, League Island, Pa. Appropriation now available, $214,000. Mordecai T. Endicott, Ch. Bureau of Yards & Docks, Navy Dept., Washington, D. C.

Jefferson Barracks, Mo.—Bids will be received at the Quartermaster's Office, St. Louis, Mo., until Oct. 6 for constructing roads and granitoid walks at Jefferson Barracks. Address Capt. W. C. R. Colquhoun, Acting Depot Q. M.

Rock Island, Ill.—The following bids were opened Aug. 30 by Maj. C. McD. Townsend, Corps of Engrs., U. S. A., for construction and repair of dams and shore protection on upper Mississippi River, *a* from Rock Island to Burlington, where ratio of rock to brush work is 1:2, and *b* from Burlington to Hannibal, rock to brush, 1:15: A. J. Whitney, Rock Island, *a* $1.19 per cu. yd. rock, 35 cts. per cu. yd. brush; Fetter & Crosby, La Crosse, Wis., *a* and *b*, $1.19 for rock and 39 cts. for brush; Albert Kirchner, Fountain City, Wis., *a* 97 and 28 cts. for rock and brush, respectively, being an average of 51 cts. per cu. yd., at which recommendation for award was made, allowing for 68,627.4 cu. yds. of work according to appropriation: *b* 98 and 29 cts., an average of 56.6, award likewise recommended, allowing for 61,837.4 cu. yds. of work.

Louisville, Ky.—Bids are wanted Oct. 4 for office and warehouse at Lock No. 1, Barren River, Ky. Maj. E. H. Ruffner, Corps Engrs., U. S. A.

Memphis, Tenn.—The following contracts are reported awarded according to bids opened Sept. 2 by Capt. E. E. Winslow, Corps of Engrs., U. S. A., for levee work: Near Helena, Ark., 90,000 cu. yds., Dresbach Bros., at 18.35 cts. per cu. yd.; Ferguson loop, 160,000 cu. yds., M. J. Roach, at 19.90 cts.

Plattsburg Barracks, N. Y.—Bids are wanted by the Quartermaster until Oct. 10 for constructing Hospital Steward's Quarters at this post.

Elmira, N. Y.—Bids will be received until Oct. 10 by Jas. Knox Taylor, Superv. Archt., Treas. Dept., Washington, D. C., for installing a conduit and electric wiring system for the U. S. Post Office and Court House at Elmira.

Wilmington, Del.—Bids were opened Sept. 11 by Col. Jared A. Smith, Corps of Engrs., U. S. A., for dredging, as follows: Coast Jetty Co., 17 Bway., N. Y. City, 25 and 20 cts. per cu. yd.; Atlas Dredging Co., Wilmington, 16, 13 and 14 cts.; John L. Grim, Phila., 19, 16 and 17 cts.

Baltimore, Md.—Bids were opened Sept. 11 by Col. Peter C. Hains, Corps of Engrs., U. S. A., for dredging as follows: *a*, Southwest Harbor; *b*, Curtis Bay: American Dredging Co., Phila., *a* 16½ cts. per cu. yd., *b* 13½ cts.; Morris & Cumings Dredging Co., N. Y. City, *a* 17½ cts., *b* 13.2 cts.; Md. Dredging & Contg. Co., Balto., *a* 14½ cts. (awarded), *b* 13 cts.; Sanford & Brooks Co., Balto., *b* 12.75 cts.

New York, N. Y.—The following bids were opened Sept. 11 by Col. S. M. Mansfield, Corps of Engrs., U. S. A., for the removal of 15,000 cu. yds. rock in Hudson River: Dunbar & Sullivan, Buffalo, contract awarded, at $3.35 per cu. yd., total $50,250; P. Sanford Ross, Inc., Jersey City, $4.75; Phelan & Co., Syracuse, $5.19; R. G. Packard Co., N. Y. City, $3.94; Kirk, Driscoll & Co., Syracuse, $5.30.

Bids were also received at same time from Kirk, Driscoll & Co. for 150,000 cu. yds. dredging at 28 cts., total $42,000; and for dike work including 3,850 cu. yds. large rubble stone, 6,600 cu. yds. ordinary rubble stone, 2,400 cu. yds. quarry spalls, 600 cu. yds. paving stone; total of bid, $56,690.

Chattanooga, Tenn.—Bids will be received until Oct. 8 at the Constructing Q. M. Office, Custom House & Post Office Bldg., Chattanooga, for constructing, plumbing, heating and gaspiping about 65 frame buildings, constituting new military post to be built in Chickamauga Park, near Chattanooga. Address H. J. Slocum, Capt. Cav., Q. M.

Washington, D. C.—Bids are wanted by the U. S. Comn. of Fish & Fisheries, Washington, until Sept. 22 for constructing an aquarium on 6th and B Sts. Geo. M. Bowers, Comr.

Memphis, Tenn.—Local press reports state that bids will be received by Capt. E. E. Winslow, Corps Engrs., U. S. A., until Sept. 30 (readvertisement) for constructing Modoc Loop levee, aggregating 150,000 cu. yds.

Burlington, Ia.—Major Townsend is reported to have recommended that the bid of Albert Fichner, of Fountain City, be accepted for improving the Burlington Harbor and the harbor between Burlington and Hamilton; his bid for the 2 contracts is reported to be $70,000.

Tampa, Fla.—Bids are wanted Oct. 6 for dredging at Orange Mills Flats, St. Johns River, Fla. Capt. Herbert Deakyne, Corps Engrs., U. S. A.

Ft. Lawton, Wash.—Bids are wanted Oct. 3 for constructing several buildings, including plumbing, gaspiping and heating at this post. Address Maj. G. S. Bingham, Q. M., U. S. Army, Seattle, Wash.

Sandusky, O.—The following bids were opened Sept. 5 by Maj. Dan C. Kingman, Corps of Engrs., U. S. A., Cleveland, for dredging the harbor: A. W. A. McGillis & Co., Cleveland; B. L. P. & J. A. Smith Co., Cleveland; C. John J. Stang, Toledo, recommended for award; D. Buffalo Dredging Co., Buffalo; E. G. H. Breymann & Bros., Toledo:

Dredging.

[illegible]	120,000 cu. yds.	200,000 cu. yds.	50,000 cu. yds.	40,000 cu. yds.	5,000 cu. yds. rock.	Totals.

MISCELLANEOUS.

Ithaca, Mich.—Bids will be received by Parker Merrill, Co. Drain Comr., care S. Thompson, North Star Township, until Sept. 18 for constructing "Hass and Brown Drain." Total length about 3 miles.

Galveston, Tex.—J. W. O'Rourke & Co., Denver, Colo., have been awarded the contract for the construction of the seawall, 17,593 ft. long, of granite concrete on a piling foundation, with sandstone riprap protection, for $1,193,318.80, taking $350,000 in seawall bonds as part payment and agreeing to complete in 15 mos. The detailed bids, opened Sept. 5, are given in the accompanying table:

Items and Quantities.	J. W. O'Rourke & Co., Denver, Colo.	J. W. Thompson, St. Louis.	Parker, Washington Co., San Antonio, Tex.
Sand excav., 106,000 cu. yds.	$.20	$.16	$.28
Round piling, 754,560 lin. ft.	.20	.15½	.19
Sheet piling, 3,800 M. ft.	30.00	25.00	31.50
String piece, 70,372 M. ft.	30.00	24.00	42.75
Reinforcing rods, 264,000 lbs.	.05	.03½	.04½
Vitrified pipe, 300 lin. ft.	.20	.50	.45
Granite concrete, 102,109 cu. yds.	7.00	7.76	8.66
Limestone concrete, 102,109 cu. yds.	6.60	7.76	7.84
Sandstone concrete, 102,109 cu. yds.	6.60	7.76	7.54
Sandstone riprap, 86,700 tons.	2.10	2.58	2.30½
Limestone riprap, 92,000 tons.	2.10	2.58	2.50
Granite riprap, 110,000 tons.	2.10	2.58	2.48
Totals:			
Granite concrete and granite riprap.	$1,247,249	$1,316,164	$1,464,837
Limestone concrete and limestone riprap.	1,168,605	1,269,724	1,338,307
Sandstone concrete and sandstone riprap.	1,157,475	1,256,050	1,277,518
Granite concrete and sandstone riprap.	1,198,319	1,256,050	1,391,880
Granite concrete and limestone riprap.	1,209,449	1,269,724	1,422,037
Time, months	15	12	18
Payment in bonds.	$350,000	$500,000	$600,000

New York, N. Y.—Bids are wanted Sept. 18 (readvertisement) for furnishing material and erecting a stone wall to complete the inclosure of the entire block and prison buildings on Leonard, Elm and Franklin Sts., including gateways, yard work, etc. Thos. W. Hynes, Comr. Dept. of Correction.

Holly, Mich.—Bids will be received until Sept. 18 by A. B. Bixby, Co. Drain Comr., at the office of M. Chase, in Holly, for cleaning out, straightening and deepening "Patterson and Holly Drain."

St. John, N. B.—The Bd. of Wks. is reported to have recommended that D. W. Clark & Son receive the contract for constructing the McLeod wharf, for $49,487.

Lafayette, Ind.—The Co. Council is stated to have decided on the improvement of Main St. levee and sidewalk. The proposed improvement of the Main St. levee is to be of asphalt, and sewerage, all water draining to the river instead of the bottom lands, as is now the case. The roadway will not be less than 60 feet, with a sidewalk on the south side; estimated cost of work, $18,000.

Syracuse, N. Y.—Three bids were opened Sept. 2 by Bd. of Contract & Supply, for improving Onondaga Creek, as follows: John Kelley, recommended for award, $26,380; Syracuse Improvement Co., $35,390; Wm. T. O'Connor, $28,595. The detail of the lowest bid is reported as follows: Bailing and draining, $10,000; clearing, $500; clearing and grubbing 2 acres, $200; 43,500 cu. yds. excav. at 28 cts.; 800 cu. yds. embankment at 25 cts.; 1,000 cu. yds. riprap at $2; 250 cu. yds. concrete at $5; 100 ft. 8-in. sewer pipe at 50 cts.

New York, N. Y.—Bids will be received by the Dept. of Docks & Ferries until Sept. 23 for dredging on the North River, between 18th and 20th Sts., also between 21st and 23d Sts.; for rebuilding the pier at E. 32d St., known as pier No. 80, E. R.; for furnishing and delivering sand and broken stone for concrete. McDougall Hawkes, Comr. of Docks.

Oakland, Cal.—The following bids are reported opened Sept. 2 for the construction of the tunnel between Alameda County and Contra Costa County, *a*, Alameda end, *b*, Contra Costa end: Clark & Henry, Stockton, *a* $37,578, *b* $51,388; Healy, Tibbetts & Co., *a* $28,290, *b* $39,243; E. B. & A. L. Stone, *a* $32,049, *b* $45,260; A. B. Munson, *b* $39,185; San Francisco Constn. Co., *b* $39,504.

NEW INDUSTRIAL PLANTS.

The Kennedy & Moorelock Stave Co., Memphis, Tenn., is erecting a stave and heading plant at So. Memphis, in which 160 H.-P. in boilers, a 100-H.-P engine and a 3-room dry-kiln, each room to be 20x104 ft., will be installed.

The Buffalo & Susquehanna Iron Co., 59 Erie County Bank Bldg., Buffalo, N. Y., is proceeding to build, at Stony Point, two 20x80-ft. blast furnaces and eight hot-blast stoves. Installing boilers, engines and other necessary machinery.

William J. Copp, Fort William, Can., is interested in a company which has begun the erection of a foundry for stoves, ranges and general castings at that place. The plant will include a 2-story, 55x110-ft. mounting shop, a 2-story, 50x40-ft. office building, a molding room about 75x125 ft., and other necessary buildings.

The Fairweight Standard Scale Co., 20 Franklin St., Danville, Ill., will erect a manufacturing plant to cost not less than $20,000.

The Commercial Envelope & Box Co., Binghamton, N. Y., is erecting a 4-story, 60x250-ft. factory, in which a 50-H.-P. gas engine will be installed. It is also expected to build a folding board mill.

The Monarch Refrigerating Co., 239-261 Michigan St., Chicago, contemplates building a large addition and enlarging the capacity of its power plant.

The Wolverine Brass Works, Grand Rapids, Mich., are erecting an 80x28-ft. foundry.

The John-Peaslee Shoe Co., Pontiac, Ill., will erect a 3-story and basement, 48x156-ft. brick factory and install an engine of about 75 H.-P.

The Laidlaw-Dunn-Gordon Co., Cincinnati, O., is building a 37x57-ft. power plant and installing a 110-Kw. direct-connected generator and tandem compound engine. A similar unit will be added later, and additional machinery as required. The company is also considering the addition of a machine shop.

The Wright Taper Roller Bearing Co., 809 Mutual Life Bldg., Buffalo, N. Y., will erect a 3-story, 216½x44-ft. factory, with 40x75 and 65-ft. additions. The capacity of the power plant to be installed will be about 225 H.-P.

The Nova Scotia Steel & Coal Co., Ltd., New Glasgow, N. S., is building at Sydney Mines a blast furnace and 80 retort coke ovens, with the necessary stock sheds, engine houses, etc. The erection of an open-hearth plant will be begun next spring.

The Bloom-Kloeb Mfg. Co., Cridersville, O., is arranging to build a 60x100-ft. foundry.

The foundry plant to be built by the Lane & Bodley Co., Cincinnati, O., will include a 120x300-ft. foundry, arranged to permit of extension; flask and pattern shop; pattern warehouse and power house. The power plant will be of about 300 H.-P., and there will be installed traveling and jib cranes ranging to 30 tons, cupolas, blowers, elevators, casting cleaning appliances, tramway, core ovens, sand mixing and sifting appliances, foundry pneumatic tools, ladles, trucks, molding machines, heating and lighting appliances.

Margolius & Co., Norfolk, Va., will erect a 75x175-ft. factory and are in the market for an 80-H.-P. engine and a 100-H.-P. boiler.

The Norton Electrical Instrument Co., Manchester, Conn., is erecting a 2-story and basement, 32x100-ft. factory, to be run by electricity of about 50 H.-P.

The International Lace Co. will erect a mill at Gouverneur, N. Y., to cover about 200x675 ft. and to be provided with steam and electrical power plant and also with electricity transmitted from Hannawa Falls. A steam heating plant, water tower and sprinkler system will be installed. J. S. Lesser & Co., 511 Broadway, New York, are interested in the company. Williams & Johnston, Ogdensburg, N. Y., archts.

W. T. Joyner, Garysburg, N. C., is interested in the formation of a company, with a capital of $50,000 to build a cotton mill.

The Durability of Steel in Concrete............ 280

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Unreasonable Contract Requirements by the Government.

On August 20th the Chief of the Bureau of Yards and Docks announced that proposals for a masonry dry dock at Charleston, S. C., would be received on October 11th, and issued specifications for the information of contractors who might desire to bid for the work and for the execution of it by the successful bidder. This is not a new procedure for the Bureau of Yards and Docks. Indeed, a number of dry docks have recently been constructed or attempted to be constructed by that Bureau. At least some of the circumstances attending the construction of such work at Norfolk and Boston are quite fresh in the minds of engineers and contractors. The operations necessary for the beginning and the conduct of this class of constructions should be familiar to the Navy Department, and it is fair to presume that the character of specifications requisite for the prompt and efficient execution of such contracts is known to the Bureau of Yards and Docks, at least to a reasonable extent. Inasmuch as the authorized cost of the Charleston dock may reach as much at $1,250,000, it is a matter of some interest therefore to the public to ascertain the real character of the proposed specifications and contract for this dock, in view of the developments which have taken place at Norfolk and Boston, Philadelphia and Mare Island, to go no further. It is even more interesting to the civil engineering profession, for the reason that the present Chief of the Bureau of Yards and Docks is the first civil engineer who has held that position.

One of the first and most marked of the features of these specifications to impress one is their indefiniteness in those particulars most essential not only to intelligent and economical bidding from a contractor, but also to efficiency in the execution of the work and the safety of the dock after completion. If there is any one thing which experience in foundation and other similar constructions has brought forth it is the imperative necessity of the most complete and careful sub-surface examinations at the site of the proposed structure. It is further evident that the construction of a dry dock is practically foundation work of the most pronounced character, almost the whole of it necessarily being a sequence of sub-aqueous operations. Every well informed civil engineer of experience need not be told that in such a case the most complete and careful set of borings or other similar examinations should be made, with a record in detail of every feature disclosed at every point. Yet in these specifications there is practically a confession in terms that no such conclusive information is available, either for the contractors or for the guidance of the engineers in the actual performance of the work.

It is of the very essence of the functions of the responsible engineer of work, especially of so great a work as this, to elaborate in complete detail by plans and specifications precisely what is to be done, the various general dimensions of the structure, the different grades and classes of work with definite quantities on which to base comparative bids, and all other information of a quantitative character which goes to make up an accurate and correct description. In this specification, however, in paragraph 3, the bidder is advised that should he be successful, his lump sum proposal is expected to cover any omission of work or materials required, any mis-description, or almost any other fault, negligence or incompetency, if it exists, of the engineering authority designing the work and writing the specifications. In other words, the lump sum bid is expected not only to cover all legitimate work under the contract, but to insure the United States Government against the negligence, incompetency, or other shortcomings of its own officers. It is a truly remarkable feature of a set of specifications issued from the highest office of construction in the United States Navy, and it sets the pace for much which follows. A contractor must find out as he proceeds with the work what is to be done and how it is to be done, essentially compelling him to make his proposal a gamble, on the results of which will depend his profit or his loss.

It is apparently expected by the Chief of the Bureau that this condition of things will necessitate certain changes in the contract plans and specifications, and he is probably right. If such changes vary the cost of the work by more than $300, "as estimated by the civil engineer in charge," the latitude of the contractor is abruptly closed. It is made his duty to find out the errors in the plans and specifications which have emanated from the Bureau, and presumably to show how they should be corrected so far as they affect the progress of the work, but he is to have absolutely no voice in determining the cost of all these changes. Paragraph 17 prescribes that a board of three subordinates of the Chief of the Bureau of Yards and Docks shall make the determination of cost based upon prices ruling at the time the estimate is made, and if this determination is approved by the Chief the contractor must accept it "in full satisfaction for all work done under the contract." There probably could not be devised a method of constructing a great work like this in which more uncertainty, more inefficiency and less fairness and justice to the contractor could enter, nor could there be found a more unbusinesslike, unsafe and wasteful procedure for the Government. In the first place such procedures effectively repel the most experienced, responsible and skilful contractors from bidding at all, and those who do bid must either court almost certainty of heavy loss or bid so high as to reach extravagance. It is practically impossible under such circumstances for the Government to secure a successful work without inflicting loss on the contractor on the one hand, or escape being saddled with a defective and unsuccessful work at the price of an extravagant profit to the contractor on the other.

We are not disposed to be ungraciously critical or hypercritical of the Bureau of Yards and Docks; indeed, the Engineering Record labored effectively for the rational system of placing a civil engineer at its head, and it is no less convinced now than then that the system is correct and calculated to secure the most efficient results for the Government, but the procedures of that office must be consistent with the best business methods of civil engineering practice. Any civil engineer who fails to know what he wants and how to get it is not discharging his duties in an efficient and proper manner, whether he be found in the navy or out of it. It is his duty to secure complete, accurate and reliable information concerning every feature of the work which he undertakes to do and assume proper responsibility for it. If there are certain details of that information which it is not feasible for him to complete, and, consequently, corresponding details of the work which cannot be accurately set forth by the specifications, and there may be such in numerous works, he should assume the responsibility of the situation himself and not attempt to shift it to the contractor.

It is a wrong system to start with to attempt to construct a masonry dry dock, such as that contemplated at Charleston, for a lump sum compensation, especially if there are involved such uncertainties as those which the Chief of the Bureau of Yards and Docks describes in his specifications. Compensation for such work should be made on the basis of unit price for all the different classes of work or material involved in the entire construction. This leaves the engineer all the legitimate freedom which he needs to adapt the plans and specifications to every exigency which may arise, with perfect justice to the contractor and with the greatest economy to the Navy Department.

If the responsible engineer is qualified to perform his duties his estimate based upon a schedule of unit prices may be made to represent with practical accuracy the entire cost of the work far more nearly than any lump sum guess based upon such incomplete and defective information as the Charleston specifications seem to be based upon. Changes in the details of plans must occasionally be made in this class of engineering works, but they should be intelligently and fairly provided for, so as to make an adequate compensation to the contractor for any extra work which he may have to perform, or possibly the reverse adjustment, and that is perfectly consistent under proper plans and specifications with the highest degree of economy in the complete execution of the work. The invitation to receive proposals should be recalled, exact and adequate information should be completed, then the plans and specifications should be so revised as to encourage reasonable bids and afford efficient methods of contract proceedings, together with fair compensation to the contractor.

There are other general characteristics of these specifications which might be sharply criticised, but the points set forth illustrate clearly their general character. A further criticism of some of the technical details of the specifications will be made in a succeeding issue of The Engineering Record.

A Large Power Development Project recently undertaken to furnish light and power in a leading Southern city has an aspect as instructive as a fable by Æsop. The river has several good sites for a station, one of which a local promoter has been keeping before the public. Every step in his plans has been explained in the newspapers for the admiration of his fellow citizens. But one of them was wicked, organized a rival company and began building a station at a nearby site before the promoter found he was undermined, and realized too late that silence is golden.

The Eighteen Mile Creek Viaduct.

Bridge No. 9 of the New York, Chicago & St. Louis Railroad crosses Eighteen Mile Creek on a steel viaduct about 700 feet long and nearly 100 feet in maximum height. The original structure had pin-connected spans which carried one track of the New York, Chicago & St. Louis Railroad and one track of the Western New York & Pennsylvania Railway, and has recently been replaced without interrupting traffic on either road, by a plate girder viaduct using the old masonry piers and having the same center line. The new structure comprises seven 30-foot towers and eight 60-foot deck plate-girder spans, the latter proportioned for two 136-ton locomotives followed by a train load of 4,000 pounds per lineal foot on each track, and for a dead load of 1,200 pounds per lineal foot, quantities which produce a maximum moment of 1,575,000 pounds and an end shear of 116,000 pounds. The 30-foot spans are proportioned for a dead load of 900 pounds per lineal foot and develop moments and shears of 458,500 and 69,750 pounds respectively.

Each tower has four columns, battered about 1 : 9 in vertical transverse bents, and seated on separate masonry piers close to the surface of the ground. Four of the towers are about 91 feet and one is about 79 feet high from top of pier to base of rail; all are divided into three vertical panels by horizontal longitudinal and transverse struts and have rigid X-bracing in every panel. The other two towers are about 25 feet high and each face is X-braced in a single panel. Each tower has one fixed and one sliding seat for a 60-foot span, and the masonry abutments, about 690 feet apart, have fixed and sliding girder seats at the opposite ends of the viaduct.

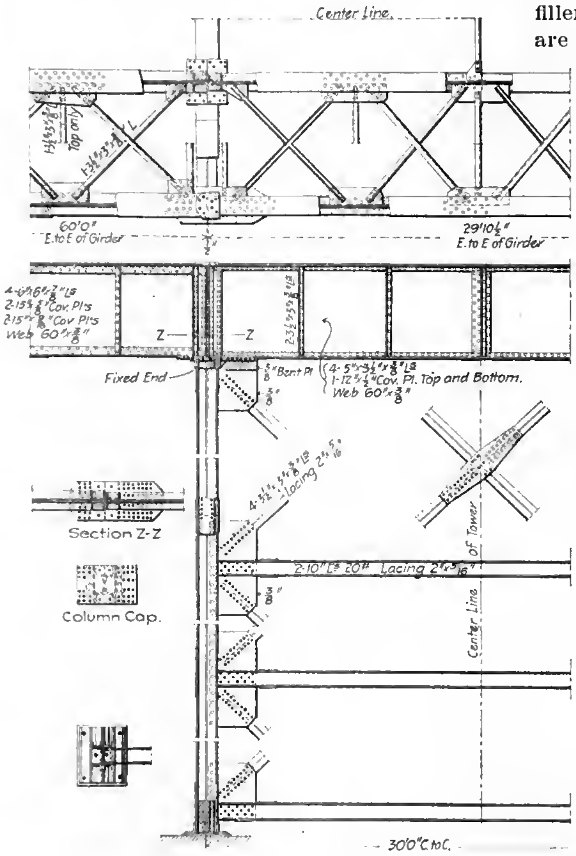
In the tall towers the maximum column compression is 380,900 pounds and the corresponding section is four 6x4-inch Z-bars and one 11½x⅝-inch web plate. At the base of the column, the web and side plates are extended to form vertical transverse gusset plates which distribute the load on a 30x38-inch base plate resting on a 32x40-inch bed plate with a ¼-inch sheet lead filler between it and the pier top. The ¾-inch cap plates are about 2 feet wide transversely and 3 feet long, and have holes for 40 field rivets connecting them to the bottom flanges of the longitudinal stringers. The columns are spliced at the bottom of the upper story with two 11x½, two 10x⅜, and four 3½x⅜-inch plates, shop-riveted to the lower sections and forming jaws which are field-riveted to the upper sections.

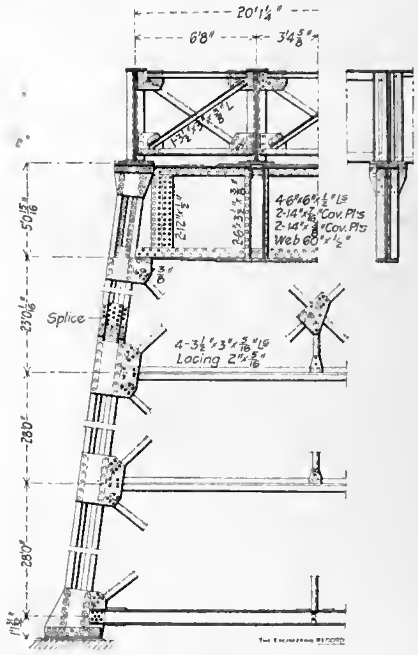
The two upper transverse horizontal struts have I-shaped cross-sections made with two pairs of 3½x3-inch angles, latticed. All other horizontal struts are made with two 10-inch channels, latticed. Pairs of rectangular connection plates with the corners clipped off are shop-riveted to the webs and flanges of the columns and form jaws which engage the ends of all struts and diagonals and are field-riveted to them. The upper longitudinal connection plates are made very long and have horizontal top flange angles which are shop-riveted to the lower flanges of the 30-foot main girders. The transverse struts are from 27 to 41 feet long and are calculated for a maximum compression of about 48,000 pounds. They are supported in the middle by vertical suspension angles from the intersection of the diagonals in the X-bracing of the panels above. The transverse X-braces are pairs of 3½x3-inch angles and the longitudinal X-braces have I-shaped cross-sections made with double pairs of 4x3½-inch angles, latticed. In all panels, one diagonal is cut at the center to clear the other one, which is continuous, and has jaw plates shop-riveted to the end of one section which engage and are field-riveted to the other section and to the other diagonal.

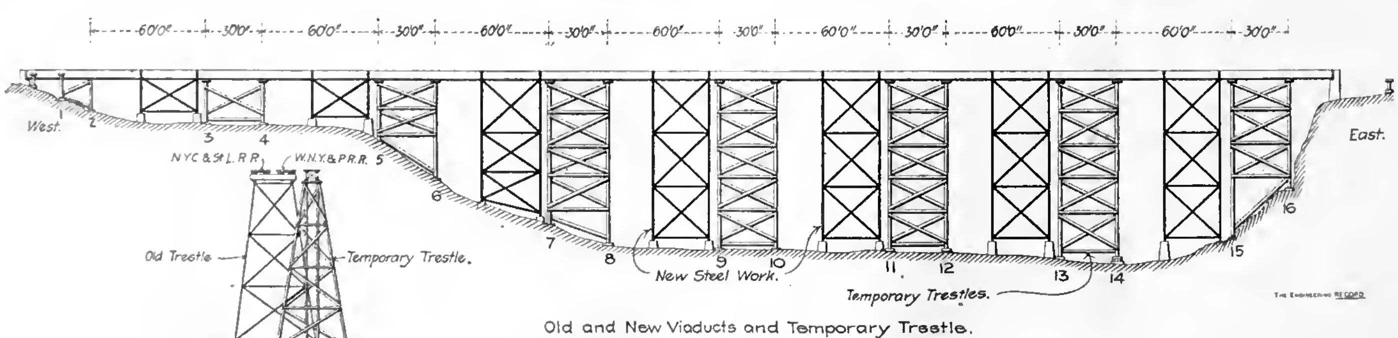
The web plates are not continuous in the upper sections of the columns but are cut off about 5 feet below the cap and replaced by plates about 3 feet wide which project beyond the inner flanges of the column in the planes of the webs of the transverse girders and are spliced to them with two cover plates with four vertical rows of rivets. These plates form jaws to receive the girder webs and have one row of shop rivets in the column plate and three rows of field rivets, thus securing sufficient spring to facilitate field assembling. The ends of the bottom flange angles are field-riveted to the extended column web plate and to horizontal shelf angles on the upper edges of the connection plates for the sway-brace diagonals.

The transverse girders have vertical stiffeners on both sides of the web in the planes of the inner lines of the longitudinal girders. Each stiffener is a pair of 6x3½-inch angles 8 inches apart, back to back, with their narrow flanges riveted to the girder web. A U-plate 12 inches wide is riveted between the tops of the stiffener angles to form a seat flush with the under side of the top flange angle. This seat projects 6 inches beyond the edge of the flange cover plate and is fillered up flush with its top to form an extended bearing for the lower flanges of the inner longitudinal girder, which has a 12x30-inch shoe plate seated on one end of a 24x30-inch bed plate across the top of the flange and fillers. In the outside stringers the shoe plates are about 20 and 38 inches long for the 60-foot and 30-foot girders respectively, and have four rows of rivets outside the flange angles engaging the bed plates at the fixed ends and corresponding bolts through slotted holes at the sliding ends.

A clearance of 1 inch is left between the ends of the 30-foot and 60-foot spans at the expansion ends, and of ½ inch at the fixed ends, and the joints between the top flanges are covered by short top plates with their edges bent down vertically to engage the edges of the flanges. The pair of longitudinal girders on each side of the center line of the viaduct are connected by vertical transverse sway-brace frames about 7 feet apart, and by top and bottom zig-zag angles between them in the planes of the top and bottom flanges. The pairs of stringers are connected together across the center line of the viaduct at every second panel, by single transverse horizontal angles in the planes of the top and bottom flanges and without any sway-brace







Old and New Viaducts and Temporary Trestle.

THE EIGHTEEN MILE CREEK VIADUCT, NEW YORK, CHICAGO & ST. LOUIS RAILROAD.

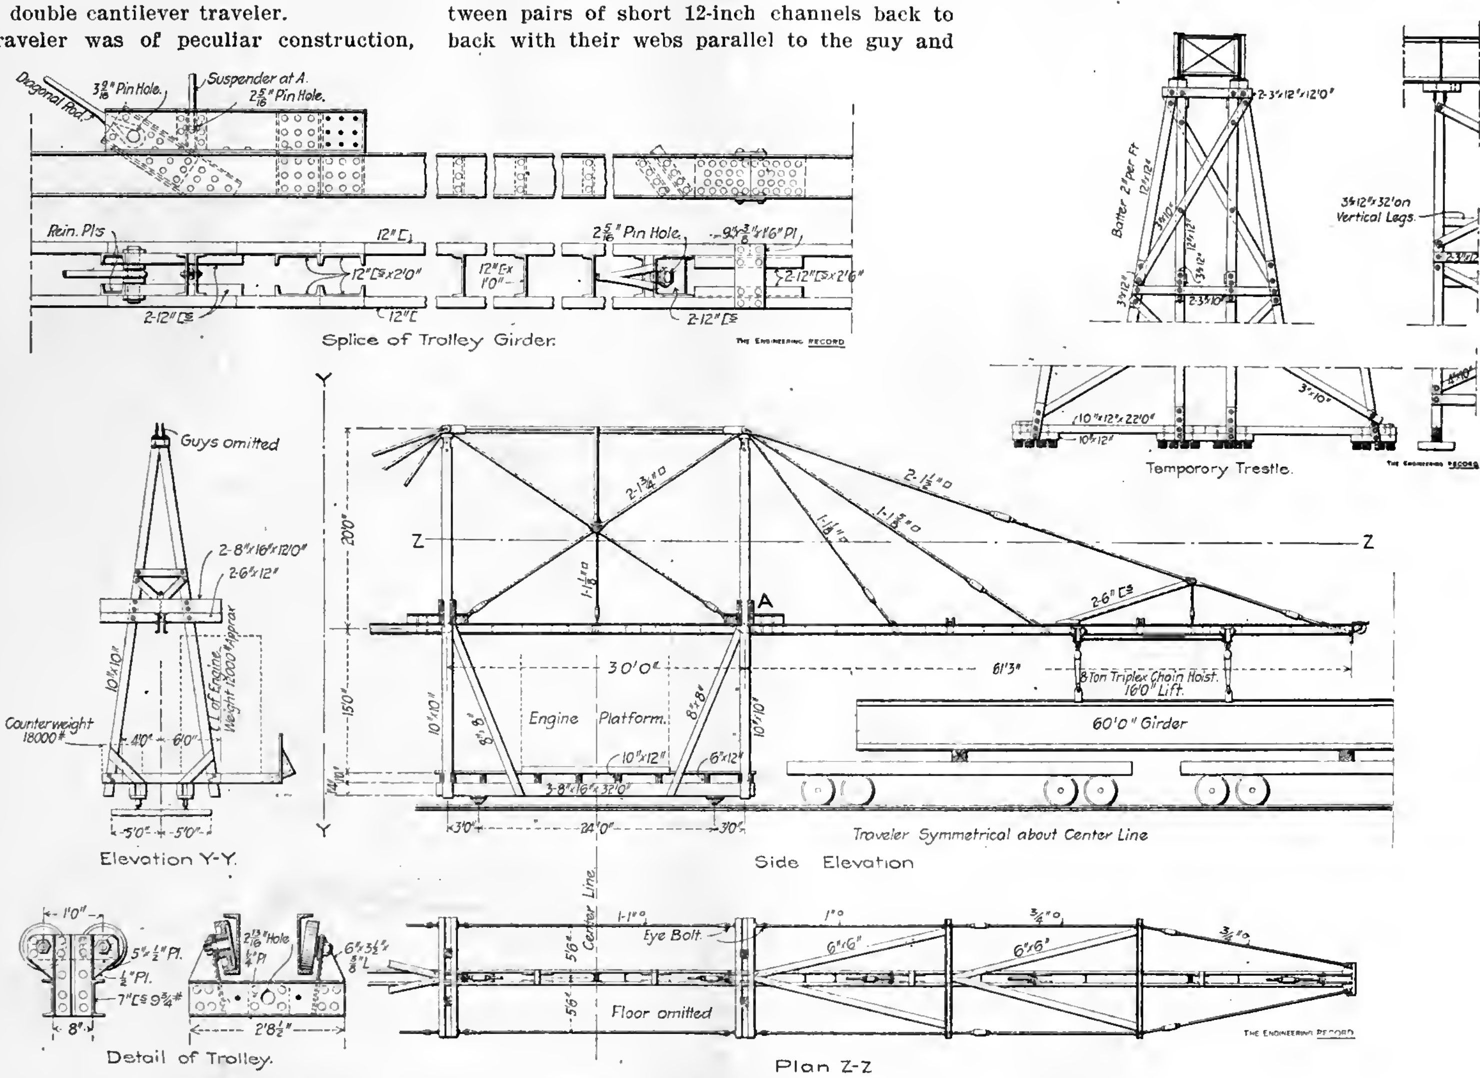
diagonals. All these braces are single 3½x3-inch angles.

Preliminary to the erection of the new structure a single-track wooden trestle viaduct was built as close as possible to the old viaduct, and interlocking with it. The new towers were placed between the old ones and had their columns on one side seated on the center line of the old viaduct. The tower tops were just outside the tops of the old towers, as shown in the cross-section, and supported lines of longitudinal girders borrowed temporarily from the new structure. Traffic was abandoned on the adjacent track of the old viaduct while the temporary trestle was being built and its members and the girders were handled at track level from one end of the structure. When the temporary trestle was completed all the train traffic was diverted to it, the old viaduct was dismembered and the new one was erected by an overhead double cantilever traveler.

The traveler was of peculiar construction, channels 12 inches apart back to back. It was made from 12-foot lengths of old stringer channels, shop-spliced with short lengths of 12-inch channels riveted across the joints, inside, back to back and had top flange cover plates. The channels were separated and stiffened by 12-inch lengths of vertical 12-inch transverse channel diaphragms with their flanges riveted to the backs of the main channel webs. The girder was shipped in three sections, the middle one being 36 feet long and reaching across the tower bents from which it was supported by suspension rods to the cross struts. The end sections were cantilever arms about 60 feet long and spliced to the center section with vertical and horizontal channels as shown in the detail.

Each cantilever arm was supported by three adjustable guy rods from the top of the tower. The lower ends of the guys were engaged between pairs of short 12-inch channels back to back with their webs parallel to the guy and projecting above the upper flange of the girder. At the ends they converged to the ends of the girder.

Two trolleys, each with four inclined wheels, ran on the upper surfaces of the lower flanges of the girder. Each trolley was provided with a shackle from which an ordinary tackle could be suspended for handling the columns and struts, and was also provided with a pin connection for an 8-ton triple chain hoist with a 16-foot lift. These trolleys were spaced by a 15-foot tie and used with the hoists to handle the 60-foot girders, which were brought on cars under the rear arm of the traveler, lifted clear, traversed to the end of the forward cantilever and lowered to place. The trolleys were traversed by the hoisting engine operating a tail rope led around a sheave at the extremity of the cantilever arm. The traveler had a total capacity of 24,000 pounds on a 15-foot wheel base,



PLANT USED IN ERECTING THE EIGHTEEN MILE CREEK VIADUCT.

and consisted of a tower about 38 feet high which supported a single horizontal trolley track about 155 feet long over all and 18 feet above the viaduct rails. The tower consisted of two A-shaped transverse timber bents 10 feet wide at the base and mounted on a pair of triple sills 32 feet long and 6 feet apart on centers. They were braced transversely by cross pieces and longitudinally by diagonal rods and knee braces. The ends of the tower cantilevered 3 feet beyond each of the four double-flange wheels which supported it on the standard-gauge track, and its sills carried floorbeams which cantilevered 3 feet beyond them on one side and 9 feet on the other side. They carried an 8x30-foot floor with the hoisting engine set on it outside the sill and counterbalanced by an 18,000-pound weight on the short ends of the floorbeams.

The overhead trolley track consisted of a single horizontal girder with two lines of 12-inch their flanges riveted obliquely across the backs of the girder channels. Their webs were bored to receive the pins in the ends of the guy rods. The upper ends of the guy rods were engaged by pins through pedestals riveted to pairs of transverse channels shouldered into the tops of the tower bents. The pedestals on the two bents were connected by an I-shaped tension strut made of two pairs of 3x2½-inch angles latticed, which equalized the reactions between the two sets of guys. The trolley girder was stiffened transversely by trussing in a horizontal plane. Wooden transverse struts were fitted to have their inner ends bear against the web at the tower bents and through their outer ends horizontal longitudinal eye-bolts were were placed to engage the ends of tension rods 11 feet apart, parallel with the girder on each side. These rods were pin-connected to the ends of spreader struts which were riveted between short vertical pairs of channels project- or of 14,000 pounds at the extremity of one arm. When in use for heavy loads the feet of the inclined posts in the tower bents were firmly wedged against blocking and were lashed securely to the completed structure to provide anchorage against eccentric loads.

After the new structure was completed except the track nearest the temporary viaduct, the traffic was diverted from the latter to the new track already laid and the girders were removed from their temporary position on top of the wooden towers and set in their permanent positions in the new structure, thus completing it and restoring the two tracks to service without having stopped any trains. In changing the last set of girders it was only necessary to reverse the process of erection. The girders were lifted by hoists on the forward arm of the traveler, run back to the end of the rear arm and thence lowered to cars on the traveler and material track underneath, which had previously served for the train traffic. The cars were run back on land and unloaded and the succeeding girders were handled in the same manner. When all were removed from the old temporary structure the traveler advanced to the end of the new viaduct alongside the completed track and receiving the girders under its rear arm lifted and passed them forward and lowered them to their final position in the regular way, advancing on the viaduct to the end of each successive span.

The viaduct was designed, constructed and erected for the New York, Chicago & St. Louis Railway Company, under the direction of Mr. E. E. Hart, engineer, by the King Bridge Company, of Cleveland, in accordance with the specifications of the New York, Chicago & St. Louis Railroad.

"Fair, Just and Reasonable Water Rates."

A few weeks ago there was printed in this journal a digest of the report of Mr. Chester B. Davis, M. Am. Soc. C. E., which was adopted at San Antonio, Tex., as a means of settling a controversy as to equitable charges for water supplied by a private company. A controversy of the same nature is now taking place between the officials of Memphis and the Artesian Water Company, and, in half of the latter a report has just been prepared by Mr. Thomas T. Johnston, which is full of interest. The following abstract of its leading features has accordingly been prepared and is here presented as an ex parte statement worthy of study even by advocates of the municipal control of all public utility services.

The basis of any estimate of just rates must be sought primarily in the amount of investment, according to Mr. Johnston. This item includes, in his opinion, the cost of planning and financing the enterprise, the preliminary legal expenses, the cost of construction and, under certain circumstances, depreciation and renewals. Whether an expenditure be classed as an investment and thus included in the capital account or whether it be termed a maintenance charge makes a difference, of course, since, if it is charged to investment, it requires an annual sum from the revenues, while if charged to maintenance it disappears. But no matter what it is called, it is represented in one way or another on the books in a sum to be met out of the revenues. It should be added that a sinking fund provision is impracticable in Memphis for local reasons.

It is held to be a mistake by Mr. Johnston not to include the amount of depreciation or cost of renewals in the investment account. This opinion, commonly held in England but rarely advocated here, he explains as follows: "This mistake doubtless is a consequence of not distinguishing between the provisions made in annual revenue for preserving the value of the plant at its original cost, and the failure to make such provisions in annual revenue. Every expense incurred, no matter what its nature, must go to investment account, unless that expenditure is at once refunded, and must remain in the investment account, with accrued compound interest, until it is refunded. Depreciation or renewals, and even cost of construction and any other expense, may not properly be an item of investment account if the equivalent money has been refunded to the investor. It is proper to contemplate that if the industry should cease, that the investor should have returned to him in the end every dollar of outlay he has made, and meantime he should have had a reasonable interest on the money and proper compensation for his services. Of course, if in the interim between beginning and closing the industry the investor has secured a revenue that is unduly large, and which exceeds 'a reasonable interest on investment and proper compensation for his services,' then just to such extent may it be equitable to make deductions from the money he should have when the industry terminates."

This view naturally leads to the following opinion of the propriety of considering obsolete portions of the plant in determining the sum upon which the rates for the service should be based: "It is questioned sometimes whether the cost of 'modifying the installation' is a proper investment charge. For instance, a pumping station may have been used at one time in the history of the plant, and was the best that could be had properly for the service at the time. Subsequent events, which could not have been certainly anticipated, or which were not anticipated, even if it was practicable, may have led to the abandonment of said pumping station. It seems perfectly clear that unless the investor had been fully reimbursed for his investment in said pumping station, the cost of the pumping station must stand in the investment account, just to such an extent as there has been failure to reimburse. It is clear that, to begin with, the cost of the pumping station was a legitimate investment charge, and must have been so considered in the fixing of 'fair, just and reasonable rates.' Its abandonment was not anticipated, so that the rates did not include any item for reimbursing the investor beyond a provision of so much revenue as would maintain the pumping station to a value equal to that which it had when new."

In the matter of estimating franchises, the opinion expressed in the report is contrary to that sometimes expressed by representatives of water companies similarly situated. It is clearly stated that no contract or franchise can have a value when it provides for fixing the rates on a "fair, just and reasonable" basis. It has been common to consider that the contract or "franchise" permitting the water company to do business, has a value. This can not be true when such contracts fix the rates on a "fair, just and reasonable" basis. The rates being thus fixed, the company has a less valuable privilege than it would have in buying land or engaging in any other industry. The contract or franchise would or might have value if it contained no limitations as to rates, or if it provided for rates that were not "fair, just and reasonable" to the city. Doubtless in some instances when it has been said that the franchise had a value, something else has been meant, as for instance, the "going value."

The nature of "investment" items being understood, the money values involved becomes a matter of evidence as to the facts, both as to the amount of money invested and as to any reimbursement therefor that may in one way or another have been made.

The annual charges relate to interest on investment and sinking fund, when there is one, operating expenses, maintenance, and the company's services.

Operating expenses when provided for by revenue—that is, when they do not go into investment account—comprise generally all expenses which do not result in a physical result, services as below described being excepted. Salaries, insurance, expendable supplies like fuel, taxes and the like, are included.

When an individual or company promotes, plans and conceives and manages an industry to the end of developing it to a physical and earning existence, it is proper that he should be compensated in money or stocks or bonds, and that the consequent expense should be charged to investment account, for the very good reason that the consequence of such service is continuous, and does not cease with the performance of the work. Not so, however, with the fireman in the boiler-room the consequence of whose labor disappears inside of a day. The value of service of this kind is entirely similar in the case of a water company, though not always expressed in similar language. In valuating a water supply plant, either for its sale or for fixing "fair, just and reasonable rates" it has been said, that in addition to the value of the physical plant, there should be added a "going value." This "going value" is nothing more or less than a measure of the value of the class of services in question.

Services of the individual or corporation, as a whole, for a useful purpose, when compensation therefor is provided for in revenue, becomes a fixed annual charge. That is, compensation is made currently instead of the cost thereof going to investment account, as must necessarily be the case prior to the revenues coming into existence. The services are of the same nature as already referred to, viz.: The service of promotion, planning, conceiving and managing; and are generally of the latter kind.

Compensation for service, while a legitimate annual charge, is not usually independently listed. In fact, no such compensation has ordinarily been made in water works practice, and has only been recognized in some cases where a sale of plant has been made to a city, and on such occasions courts and arbitration boards have recognized it under the name of "going value," or under the erroneous name of value of franchise.

Maintenance includes all annual expense not already referred to, for which provision is made in the current revenues, and in general refers to preserving, by repairs and renewals, the physical plant, so that it will at all times be as valuable as when new. Quite frequently provision is made in the revenues for but a part of such expense, in which event the part not provided for should become an item of investment account. This fact is often overlooked, much to the disadvantage of the investor.

Maintenance nullifies depreciation. It even improves the value of physical installation in some instances, in which event the increase in value should not be a factor in determining interest on investment, nor should it appear, if at any time it is desired to place a value on the industry. If the value of such improvement be deducted from maintenance expenses, provided for in revenues, of course said value should enter into investment account just as any other item.

The revenues should be equal to the annual charges as above described, and it is premised that they are derived from a "fair, just and reasonable rate" for supplying water or delivering whatever product the industry may produce.

This "rate" is to be made up of a number of distinctly different items, each of which may be greater or less according to what the gross revenue is to be. It is, therefore, necessary to determine first what gross revenue per year will be "fair, just and reasonable." It has already been shown that a greater or less portion of the expenditures in any one year may go into investment account, according to whether or not they are provided for in the revenues. It therefore becomes necessary to determine primarily and definitely what class or proportion of the expenditures in any one year it is desired or practicable to provide for in the revenues. If a large extension of the physical installation is to be made, then it may be entirely impracticable to provide for it in the revenue for immediate reimbursement, and it must in part or wholly go to investment account, and stay there to a greater or less degree according to any reimbursement that may from time to time be made.

Good business policy dictates that the annual "revenue" be made to meet the "annual charges" as nearly as it is practicable to anticipate or predetermine them, and for purposes of discussion it will be assumed that no increase of investment account is to be made except for additions to and extensions of the physical installations, and, further, that no attempt is to be made to diminish the existing investment account by providing a sinking fund or otherwise from annual revenues. These premises being adopted, it becomes evident that the question involves a consideration of the past as well as the future. The past is involved only in so far as the existing investment account is concerned. The future is involved in relation to increase of investment account, and as to the annual charges in addition to interest on investment.

The existing investment account which involves the past is the present value of the plant, and this value is determinate and can be represented by but one sum of money. It has been sometimes stated that the value of the plant may be one thing if a sale or purchase be contemplated, and that it may be another thing if the said value is to be used as a factor in fixing water rates. Manifestly, such a statement is incorrect. The investment account, made up in manner and form as hereinbefore stated, is the present value of the plant, and can be nothing more or less. Failure to perceive this fact has led to erroneous methods of estimating the present value of the plant. The present value of the plant can not possibly be determined by what has physical existence at the present time. It can not be reasonably determined by a simple consideration of the present market values of the materials or parts comprising the physical installation. A value very much greater or very much less than the true value might thus be ascertained.

Neither can the simple market values of the materials or parts of the physical installation at any time in the past be taken as a complete measure of the present value of the plant. And, further, in case any market values, past or present, may be a measure of present value, there is no reason for deducting from such market value anything on account of depreciation, unless the revenues of the past have reimbursed the investor to the extent of such estimated depreciation, or unless the revenues of the past have provided a sinking fund that may be used to renew the physical installation to such an extent as it may have depreciated in value.

Services rendered in the past, the present evidence of which are not in physical form, and the performance of which can be discovered only by examining past records, must form a part of the present value of the plant.

Finally, all of the elements of investment account as hereinbefore described, must be considered in determining present value, no matter what the purpose of ascertaining said value may be.

The present value of the plant has been agreed upon in view of a sale to the city. This does not necessarily mean that the sum will be the total cost of the plant to the city. It may be that the water rates of the past have not been sufficient to meet all proper annual charges, as hitherto defined, and consequently that a further sum would be needed for repairs and renewals in order to bring the plant up to a condition of permitting the best economy in operation. This is no fault of the water company, if it be the case, because its rates, fixed by contract, will not have been sufficient to permit a better condition of things; that is, the rates have not been "fair, just and reasonable." In other words, the water consumer has been profiting unfairly at the expense of the proper value of the plant, and in all fairness he should make good his error. Should this further sum need to enter into consideration, it will be a good item of investment account, and may be merged with other investment accounts to be involved in the future.

The remaining portions of the report are of such a local nature that it is unnecessary to refer to them.

Alternating-Current Electric Railway Operation.

An important innovation in power distribution and application for interurban electric railway service has been undertaken by the Washington, Baltimore & Annapolis Railway Company, which is to operate, by alternating current apparatus throughout, a 40-mile line between Washington and Baltimore with a 15-mile branch to Annapolis. The equipment will be the new system which the Westinghouse Electric & Manufacturing Company has been developing and testing during several years back, under the supervision of Mr. B. G. Lamme, its assistant chief engineer. In the ordinary method of operating street railways, direct current is fed to the trolley line for the car-motors. For city lines and densely populated districts, the current is often generated as direct current, but for long distance inter-urban roads this would involve a cost of copper conductors entirely prohibitive. To meet the latter objection a system has been used thus far in this country involving the generation of alternating currents at high pressures of from 10,000 to 30,000 volts and the transmission of the same to substations, where by means of transformers and rotary converters, the current is supplied to the trolley wire as direct current as the usual railway voltage from 500 to 650 volts. The rotary converters substation, however, has always been an undesirable feature, chiefly on account of the cost of the apparatus and building and the attendance required. The plans that have been proposed to do away with this feature are numerous.

In Europe the polyphase induction motor has been used to some extent, but it implies the use of two or three overhead wires, and, moreover, the characteristics of the induction motor in regard to starting and average efficiency in railway service are said to be not of the best. Other systems which have been proposed involve the use of single-phase motors upon the cars, driving generators which in turn supply power to the motors on the axles. However, this involves the placing of a substation upon the car itself, and so cannot be considered a great improvement over the ordinary alternating and direct current system. Details regarding the new system of the Westinghouse Company are not at hand, but its use is expected to avoid the limitations of the induction motor and the disadvantages of the multiplicity of overhead conductors as well as the great cost of the system just described.

For the road which is now being constructed between Washington and Baltimore, single-phase, alternating current will be generated in a 133x203 foot main power house located at Hyattsville, by three 1,500 kilowatt, single-phase, Westinghouse generators, delivering current at 15,000 volts and driven by cross-compound condensing Hamilton-Corliss engines. This station is of more than average size and is in no sense experimental. The power house will be built of brick with stone and concrete foundation, and will contain in addition two 125-volt direct current generators to be used as exciters for the alternators and a large switchboard with electrically operated oil switches, circuit-breakers, lightning arresters, etc. Current will be distributed from the power house at 15,000 volts to transformer stations located at suitable intervals along the line. These transformer stations will contain only stationary transformers with the necessary switches and fuses, but no moving machinery, and will therefore not require the presence of an attendant. From these stations current will be fed to the single trolley wire at 1,000 volts. The pressure of 1,000 volts which has been adopted for the trolley wire is not a necessary part of the system, as a much higher voltage could have been used if it had been deemed advisable by the engineers of the road.

The cars will probably be sixty feet in length and weigh about 50 tons each. They will be supplied with Master Car Builders' trucks designed for high speed, the track is laid with 80-pound rails and it is expected that the distance of thirty-one miles will be made in 45 minutes, including stops. The cars are to be equipped with four motors, each of 100 horse-power, and it is expected that a normal speed of 40 or 45 miles can be attained, and a speed of 60 miles reached when necessary. The motor, which is the novel part of the equipment and the key to the entire system, is a variable speed motor having characteristics adapted to railway service and reported to be equal in all respects to the present direct-current railway motor.

It is to be remarked that this latest development in electric railroading follows in a path already traced by electric lighting. The first electric lighting systems employed direct current at low voltage, but as the area to be supplied increased, this involved a cost of copper cables. To meet the difficulty alternating current distribution at high voltage was adopted, with rotary converter substations to enable the current to be distributed on the existing mains as direct current. However, most electric power plants now being installed distribute low voltage alternating current directly to the lamps and motors, thus avoiding the expensive rotary-converter substations.

The engineers of the new road are the Cleveland Construction Company, of which Mr. Will Christy is president. The officers of the Washington, Baltimore & Annapolis Railway Company are Mr. W. H. Lamprecht, president, and Mr. Otto Miller, secretary, both of Cleveland. The directors are as follows: Messrs. W. H. Lamprecht, F. T. Pomeroy, F. N. Wilcox and Otto Miller, all of Cleveland, Mr. Will Christy, of Akron, Mr. James Christy, Jr., of Washington, and Mr. W. L. Marbury of Baltimore, Md. It is also stated that Messrs. Henry Everett, E. W. Moore and W. J. Mandelbaum & Company of Cleveland, are largely interested in the enterprise.

The New Ash Carts used by the Street Cleaning Department of New York are required to conform to the following specifications: The body is to be a sanitary one without tailboard, and is to be of ⅛-inch steel, fastened with ⅝-inch rivets, and have 1¾x1¾x3/16-inch angle iron about the sides and front at the top and a ½x3-inch stiffener on the rear edge. The cart body is to hold 1⅝ cubic yards level full. The cart body rests on trunnions, housed in trunnion beds on top of semi-elliptic springs mounted over the cart booms. These springs are to be 32 inches over all and have 8 leaves of 2¾x¼-inch steel each. There is to be a seat board on top of body, and the booms, which are to be of first quality oak, are to have managers attached. The axle is to be 2½ inches square. Wheels are to be Archibald make 4 feet 6 inches diameter, and have 2½-inch spokes and 3x⅝-inch round edge tires.

Notes on Irrigation Engineering.

Extracts from testimony by Elwood Mead before the U. S. Industrial Commission.

Losses of Water by Seepage.—In all of the West except southern California irrigation ditches and canals are unlined. The soil over which the water passes is expected to retain it in its channel; but there are cases where it fails to do this and the losses from seepage and percolation are excessive. Where canals cross strata of coarse gravel, or where there are gypsum deposits, the losses from this cause are very great. In one instance the measurements of the Irrigation Investigation of the Agricultural Department showed a loss in a canal of 75 per cent. of its entire supply in a distance of less than a mile. The following, taken from the report of these investigations for 1899, shows the extent and character of these losses over a widely distributed area:

In practice the losses in canals from percolation, leakage of flumes, evaporation, etc., are an important factor in fixing the average duty of water from a river or an extensive canal system. To determine this average duty the volume should be measured at the headgate, and the acres it irrigates is the duty which canal managers have to consider in determining the area their works will irrigate. This duty is much lower than that obtained by measurements made on laterals or at the margins of the fields where used, the influence of the losses between the headgate and the heads of laterals being greater than has usually been supposed. Where canals cross gravel beds or gypsum deposits the results closely resemble trying to carry water in a sieve. The following table gives the number of acre-feet used in the irrigation of an acre of land where the measurements were made at the canal headgates, and include the loss from seepage and evaporation:

Duty of Water when Losses in Main Canals are Included.

Name of Canal.	Acre-feet.
Pecos Canal, New Mexico	6.61
Mesa Canal, Arizona	3.81
Butler Ditch, Utah	6.24
Brown and Sanford Ditch, Utah	5.32
Upper Canal, Utah	6.30
Amity Canal, Colorado	4.92
Rust Lateral, Idaho	5.06
Average	5.47

A comparison of the duties in the above table with those obtained when the water was measured where used will show that more than twice as many acre-feet were required where the water was measured at the headgate as where measured at the place of use; or, in other words, the losses in the canals from seepage and evaporation amount to more than one-half the entire supply. This is in accord with many of the measurements made on irrigation canals in India. Among those recorded in Buckley's Irrigation Works in India is one which shows that the irrigation of wheat under the Jamda Canal, in Bombay, required 5.6 acre-feet of water for each acre irrigated where the water was measured at the head of the canal, but where the water was measured at the place of use it required, in two experiments, only 2.1 acre-feet and 1.4 acre-feet to irrigate an acre, the loss in the canal being more than 50 per cent. On the Hathmati Canal, in the same country, the loss from the seepage and evaporation was 50 per cent. These losses in transit are much heavier than is the rule on the older canals of India, and are doubtless more general than they will be in this country when the banks of canals are older and when they are operated with greater regard for economy.

The report of Mr. Reed shows that 47.7 per cent. of the water turned in at the head of the Pecos Canal reached the consumers, while 52.3 per cent. was lost through seepage and evaporation. The causes of this loss are explained to be the checking of the velocity in the canal by dams in order to throw water on ground too high to be irrigated without this, certain defects in construction, and the nature of the soil in which the canal is built. The canal has a bank on one side only. This has produced stagnant lakes and pools on the upper side wherever the canal crosses ravines, or where the ground on the upper side is so low that the water overflows it when the canal is filled. Mr. Reed's report also shows the variation in rate of seepage due to the character of the soil, three-fourths of the water entering one section of the canal 1 mile long being lost. To his summary of the causes of the great loss of water there may be added the fact that the water used in this canal is taken from the reservoirs. Its temperature is already above that of most mountain streams, which facilitates alike its rapid filtration and evaporation. It is perfectly clear, owing to the fact that all of the sediment carried by the river is deposited in the reservoirs. This canal affords an illustration of a lower duty on a particular farm, measuring the water at its margin, than the average under the main canal, measuring the water near the headgates. Mr. Reed points out the causes for this, and shows that it does not illustrate the necessities of irrigation, but the possibilities of waste under encouraging conditions.

The water taken into the Mesa Canal during the four years that measurements have been made has varied from enough to cover land to a depth of 5.9 feet in 1896 to 3.8 feet in 1899. A measurement was made in 1899 of the water used on a farm where the land had not before been irrigated, and where more than the average amount of water was required. Owing to the fact that rotation was practiced on the lateral leading to this farm, it is impossible to determine the exact quantity lost in passing through it, but the water delivered at its head for this farm would have covered the land to a depth of only 2.8 feet. The difference between the average depth under the main canal and the depth of water used on this farm was just 1 foot, or a difference in quantity of 1 acre-foot per acre irrigated. Mr. Code estimates that this difference would have been much larger if the loss in transit through the lateral had been determined. As it is, this shows a loss of over 25 per cent.

The construction of the Gage Canal is such as to make losses through seepage practically nothing, owing to the canal being cemented. The loss from evaporation is also small, because the canal is deep and narrow and has throughout its length a uniform cross section, with no pools of still water on the upper side. As compared to losses varying from 25 to 75 per cent. shown in other canals, the loss of only 6 per cent. in this canal has great significance. The water turned into the head would have served to cover the land irrigated to a depth of 2.24 feet, while the mean depth for the water delivered to irrigators' laterals was 2.11 feet, a loss of only 0.13 of an acre-foot per acre irrigated. Canals can only be cemented on earth, as is done in California, in localities where frosts in winter are not severe. There are other remedial measures which can be employed in other sections which will, no doubt, be largely adopted when the extent of the loss from this source is more generally realized. Dumping clay into the canal and causing it to be distributed by agitating the water has been tried with good results on some Nebraska ditches.

The report of the careful and interesting investigations of Professor Fortier at the Montana Agricultural Experiment Station shows that in Middle Creek Canal nearly 22 per cent. of the total flow was lost in seepage in the first 4 miles, while the probable loss in the entire canal was 35 per cent. The conclusions of Professor Fortier are in accord with those of other observers as to both the evils resulting from this loss and the methods by which it may be reduced.

The water taken into Logan and Richmond Canal would cover the entire area it irrigates to a depth of 3.59 feet. The water actually used on the Cronquist farm would have covered it to a depth of only 2.6 feet, the difference between the average duty under the canal and the measured duty on one farm under it being nearly 1 acre-foot of water for each acre irrigated, or a difference of about 28 per cent. It is believed that this can be fairly taken as the loss resulting from the seepage and evaporation in carriage.

The water entering the headgate of the Amity Canal in Colorado would have served to cover all the land irrigated to a depth of 4.92 feet. The water delivered from the Biles Lateral would have covered the land under that lateral to a depth of only 1.82 feet. The difference between the average duty under the canal and the special duty under one lateral is 63 per cent. This seems to indicate that more than one-half of the water taken from the river disappears before it reaches the place of use. An examination of the map of the Amity Canal will show the reason for this excessive loss. The canal is a large, long one and much of the time last season was only partly filled. More than one-half of the time the water flowing through it was spread out in a broad, thin sheet, which reduced its velocity and gave abundant opportunity for the continuous sunshine to raise the temperature. This increase in temperature facilitated both its disappearance in the air and its filtration through the soil. Mr. Berry's report shows that the season of 1899 was unusually windy, making evaporation greater than usual.

Enough water was taken into Canal No. 2 at Wheatland, Wyo., to have covered all the land irrigated to a depth of 2.53 feet, while only enough water was delivered through the J lateral of that canal to cover the two fields on which the water used in irrigation was measured to a depth respectively of 0.7 and 1.55, the apparent loss in the canal being one-half the water entering it. In this case this high rate of loss is what might have been expected. The canal is long. It traverses a steep hillside slope for two miles, in which distance the loss under the lower bank is excessive. In many places the bottom is gravel, through which water escapes freely.

In order to more carefully study the variations in these losses, arrangements were made early last season by Frank C. Kelsey, city engineer of Salt Lake City, Utah, to measure the seepage loss from the Jordan and Salt Lake Canal from the Jordan River. This canal is 29 miles long, with a bottom width of 20 feet. It originally had a grade of 2 feet per mile, but when measured was in bad condition, with a flow of 30 cubic feet per second at the head. The loss in 29 miles was 45 per cent.

The losses from seepage in new canals are excessive. For the past six months 500 inches of water have been flowing in at the head of a 10-mile lateral built at Billings, Mont., in 1899, but as yet not a drop has reached the lower end. On a canal built in Salt River Valley, Wyoming, there was a loss, in 1896, of 10 cubic feet per second in a distance of 100 feet, which continued for several weeks with no apparent prospect of the loss diminishing. This was about one-third of the canal's flow. The canal was then abandoned. The canals which take water from the North Platte River are all subject to excessive losses when first built, because of the sandy soil through which they must pass. In high water, however, this river is heavily charged with a white clay, due to the erosion of its banks. When this is deposited on the sides and bottom of ditches it forms a coating only less impervious than cement, and after a few weeks' operation during high water seepage losses always show great diminution.

Mr. Code reports that the water of Salt River, Arizona, contains a cementing material which in time renders its banks almost water-tight, so long as they remain undisturbed. This has not heretofore been possible on the Mesa Canal, because it has been undergoing constant repairs and improvements.

Filling of Canals by Silt.—The canals taken out of the lower portion of those streams running out on the plains are more or less troubled by the moving sands in the bottom of the stream, that tend to fill them up; and all canals that are taken out of rivers that carry considerable quantities of mud in high waters have to be cleaned out every year. The deposits of mud can be handled as a rule without any excessive expense, but in streams like the North and South Platte and the lower part of the Arkansas the sand question is quite troublesome; and on the lower part of the Rio Grande the question of mud becomes an important factor. The red rise in the Rio Grande occurs when there are torrential rains along certain portions of the river where there is a red soil, and enormous volumes of mud are washed down in the river. Samples of the stream taken at that time have shown as high as 17 per cent. of solid matter. All the ditches have to be closed during the time of the red rise because they would immediately fill up.

At Las Cruces, N. Mex., is one of the oldest ditches, if not the oldest ditch, in the United States. That ditch was formerly a channel cut below the surface of the ground. Now it is raised 4 or 5 feet above the surface of the ground. As the mud which was carried into the ditch was cleaned out each year it was thrown on the banks; and when the banks became so high as to be troublesome they simply let the mud fill up a foot or so in the bottom. In time the ditch got above the stream, and they had to move the head farther upstream. In the period of operation of that canal the head has been moved upstream 3 or 4 miles from the original location. Not only that, but since the time the irrigation began the level of the soil on which the water and mud has been spread has been raised from a few inches to 2 feet—higher, of course, nearer the ditch, and becoming thinner and thinner as you recede from it. The Rio Grande at El Paso has filled up its channel from this cause until the river itself is higher than some of the streets of either El Paso or Juarez.

Filling of Reservoirs by Silt.—A great many streams are torrential in character, carrying an immense flow of water and then running down to nothing. You must store these streams in order to make much use of their waters, and the problem of storage is a complicated one. It involves the question of the sediment in these Southern streams—the silt. It is disastrous to build a reservoir in the channel of a river, and, when you have a large investment in houses and people settled there, to have it filled up and necessitate these settlers moving out. It is simply a waste of energy and a waste of money. That is a question that the Department of Agriculture is studying, and arrangements have been made with the agricultural college of Texas to gather samples from these streams and see what would be the probable result of letting the mud they carry deposit on the soil.

The total evaporation from the water service in the West ranges from 3 to 6 inches per month. Where the waters of the river itself are heavily charged with alkaline salts this evaporation will so concentrate them as to make it injurious; but there are very few instances of that kind. The only one that I know of personally is the Pecos River, and I think that action only occurred in one season. I do not think that would be a very important question. The streams carry so little alkali in the portion of the country where the water is stored that the accumulation would not amount to much. Then the water is discharged every year and there is no cumulative action. It is only the concentration that would take place in a single season.

Unit Costs of Work in Progress.

At the last convention of the American Society of Civil Engineers there was an important discussion on the possibility and desirability of keeping accounts of cost of work in such a manner as to ascertain the unit costs on each class. The importance of such a system of accounting to the engineer and contractor cannot be overestimated, and the full text of the discussion is accordingly reprinted from the "Proceedings" of the Society for August, page 546. The discussion was opened by a short paper by Mr. Samuel Whinery, as follows:

Two questions are embraced in this topic: The first relates to the possibility and the second to the desirability of account-keeping intended to disclose the unit cost of work.

The first of these questions has been practically answered by actual experience. Except possibly in some cases where abnormal conditions prevail, it is entirely possible to keep accounts which will show correctly the unit cost of any work, whether that work be in the nature of surveys or other preparatory operations, or of the construction of engineering structures or of manufacturing. Such accounts are now, not only common, but almost universal, in all well managed enterprises. Like all other forms of accounting, the value of the results attained will depend upon the adequateness of the general plan and details of the scheme of accounts adopted, the fidelity and accuracy with which the original records are made, and the ability and skill with which these records are compiled and deductions made therefrom.

Each of these three subdivisions of the work is of equal importance, and if either is defective, or neglected, the results attained will be unsatisfactory or entirely worthless. To devise a scheme for a cost-keeping account, with all its necessary details, and to prepare full instructions for its operation, is by no means a simple thing, requiring as it does a very intimate knowledge of the method of conducting the particular kind of work on hand. The difficulty increases with the complexity of the work and the number of unit cost items it is considered necessary to ascertain. It is only after one has had an extensive experience on similar work that one can frame a scheme that will be workable and efficient. It must be simple and easily understood; otherwise the employees who must be depended upon to make the original records will get them hopelessly confused; or a disproportionate amount of time and labor will be consumed in making them. It must be explicit in its details and instructions, for the same reason, and it should be so comprehensive as to disclose where every item of money or labor has been expended. But however perfect a cost-keeping scheme may be devised, it will prove worse than useless if not intelligently and implicitly adhered to by those whose duty it is to make the original entries or records. Every cent expended upon the work, whether in the form of cash or labor, must be accounted for and charged to its appropriate item. This sounds simple enough, but only those who have had exasperating experience with the stupid or negligent employee can appreciate how difficult it is to have these original records properly made. Assuming a good system of accounts and accurate original records, their value will depend upon the care and fidelity with which the original information is compiled and made available for use. In the press of other office duties this part of the work is often neglected or postponed until such a mass of it accumulates that it is then abandoned, or it gets into such a state of confusion that it is difficult or impossible to disentangle and tabulate it, and it is then thrown aside as worthless, with the statement that the problem of determining unit cost is hopeless.

It may be confidently asserted that, with the same amount of care and accounting skill necessary and usual in a first-class mercantile establishment, it is possible to determine with accuracy the unit cost of any engineering work.

A knowledge of the unit cost of work is of value in many ways, and accounts which enable us to ascertain it are therefore desirable. To the engineer engaged in designing modern work the important problem is how to accomplish the object sought with the least expenditure of money. Other things being equal, that particular detail will be used which is the cheapest. In order to determine which is the cheaper of two details the unit cost of each must be known. The engineer, therefore, finds it important to accumulate the largest possible fund of cost prices. To the contractor or the manufacturer the question of desirability is synonymous with the question "will it pay," and among the more enterprising and intelligent there can be but one answer. The question of success or failure in these times of sharp competition and low prices may depend upon the accuracy with which cost has been estimated, and this again will depend upon the knowledge of unit cost under the conditions that are to be met. These conditions vary greatly upon different pieces of work, and in different localities, and the estimator needs the accumulated knowledge that comes from habitual cost-keeping. It is important, therefore, that this branch of accounting should never be neglected on engineering work. Furthermore, it is important during the progress of any extensive work. The contractor or the manufacturer who has before him at the end of each week the unit cost of his work during that week can know whether it is being done with proper economy, and, if it is not, he can ascertain the cause and apply the remedy at once, and thus prevent accumulated losses. Accurate accounts will often disclose defective management which may not be detected by personal observation during the progress of work.

Mr. Charles S. Churchill stated that inasmuch as engineering is the power of producing the greatest and most permanent results for the least ultimate cost, even the intimation that actual and detailed costs cannot be determined and kept is a stroke against the foundation of the profession. The keeping of and knowledge of these detailed costs and ultimate values really constitute the greatest care of the successful engineer, and the proper use of this information is of almost equal importance.

To be told that a certain piece of first-class ashlar masonry cost $6.50 per cubic yard may attract attention; but this fact is not of much value unless we know, further, how this cost is made up, as it consists of the price of the stone delivered at $2.35, and labor on the same, with other materials, aggregating $4.15. But we are still not at the bottom, because the cost of cutting different stones varies, and the other materials also vary in cost. Therefore our information is not complete until we know that the amount, $4.15, is made up of cutting, $1.14;

laying, \$2.26; cement, 20 cents; sand, 7 cents; handling, 16 cents; and setting derricks, etc., 32 cents; and, finally, for comparison, it is necessary to know that on this particular work which has been cited the foreman mason received 30 cents, the regular masons, 25 cents, and the helpers 15 cents per hour.

Considerable care is required to keep and compile such figures; but they are of the utmost importance. For example, the cost of cutting a given stone, together with its delivered price, determines whether or not it can be used in a certain work as against stone from a different locality.

The great increase in the earning power of railroad properties in this country is the subject of wide comment. On any given railroad this increase of earning power began with the carefully-planned improvements in grades, alignment and strength of roadway, properly executed by the engineer. It was further secured by having the improvements completed at the lowest ultimate cost; and, finally, by the engineer providing many facilities for keeping down all items of maintenance cost. Referring now particularly to this last factor, we find that a spirit of rivalry exists in every good workman, and this may be brought into practical use, even if the employee be no higher than a track laborer. It is useless to depend wholly, for the best results, on driving such laborers and their foreman; and the same statement applies to every man worthy of employment on a railroad.

On some closely-operated railroads this plan is followed in much detail and with great success. For example, a simple statement is issued monthly by such a railroad, showing the actual cost of such hum-drum work as the putting of a tie in track on each roadmaster's division of the road. A rivalry is at once induced among all the foremen of every division to be the lowest. A similar statement giving the cost of placing lumber in bridges per thousand feet, B. M., in making repairs, brings about the same rivalry among carpenter forces; and all this produces an absolute and proper reduction in cost of maintenance.

Mr. T. Chalkley Hatton stated that there would seem to be only one side to this question: How can any engineer give his client a reliable approximate estimate of the cost of a proposed piece of work, unless he has first taken very careful estimates of the cost of preceding and similar work? Mr. Churchill mentioned the results of taking careful estimates of costs in relation to railroad maintenance and railroad construction, and the care with which such records have been made. The same results had been obtained by the speaker with relation to public work.

Some twelve or thirteen years ago he designed a system of sewers to cost about \$1,750,000, and to be constructed from year to year as the funds might become available. When the work began, no reliable approximate costs of the work could be made, as it was to be done under all kinds of conditions; but, at much expense, a systematic record was kept of the actual cost of excavating each linear foot of trench under each condition, whether in rock or wet ground, and whether in paved and unpaved streets; the actual cost of brickwork per linear foot, for each size of sewer and each foot of pipe; and the cost of each manhole, inlet and every other appurtenance, until, at the end of three years, the speaker had compiled a record of actual costs which enabled him to determine, within 1 or 2 per cent. the probable cost of the remainder of the work. These records were compiled in such a manner as to enable him to determine how many bricks could and should be laid by a bricklayer under the several conditions; how many feet of pipe of the various sizes should be laid per day, and the quantity of cement and hemp required to lay it; how much trench one man should excavate in a day, and how much per cubic yard it cost to remove rock.

At the end of three years it was found that the contractors were making too much profit, and the speaker recommended that the minor portion of the system be built by day's labor, and that the larger work, requiring special plant, should be done by contract. This work proved so successful that it was determined to do all work by day's labor, with the result that the contractor's profit was saved in every instance. A contract would be let out to build in one street a sewer which was of the same nature as was being built upon another street by day's labor; and this proved the case clearly.

The keeping of these accounts had the following result: Each foreman, when his particular work is finished, knows just how much it has cost, and, if this cost exceeds the cost of similar work under another foreman, he knows at once that he is not up to the standard, and a continuance would mean the loss of his job; but, aside from this fear, this system makes each foreman an enthusiastic worker for a reputation, and results in a financial benefit to his employer. If the cost of each superintendent's work is not made known to him, what means has he of knowing whether his work is or is not successful? And unless the engineer keeps a careful record of the cost, he cannot give the foreman such information, and the burden finally falls upon him.

Mr. Oberlin Smith said that it might be of interest to change the point of view to indoor work, and speak of manufacturing cost in factories; the speaker's experience having been more particularly in that line. There is a very common belief that manufacturers make enormous profits; that people who run machine-shops, and make goods that outdoor people have to handle afterward, are getting fortunes —not small fortunes, but big ones. It is a common idea, when people send to a machine-shop to have repairs done or machinery built, that if the charge is made by the hour, at say 50 cents or more, there is a profit of about 100 per cent. The ordinary public, and perhaps even some engineers who do not have to do the work, are apt to say: "Behold! Their men are paid 25 cents an hour, and they charge you 50 cents, a very nice thing in profits." But they ignore the little items of fixed charges, about which much is not generally known by outsiders. These, however, as a matter of fact, sum up to a very large amount. If we consider a medium-sized machine-shop, employing say one hundred or two hundred men, where (there being a good many boys) the wages average, perhaps, only 20 cents an hour, the expense-rate, or hour's burden, that has to be put on each and every hour worked by producers, is usually about the same amount. That is to say, the sum paid for wages upon a job must have about 100 per cent. added to cover ordinary running costs. One modern way, therefore, of finding costs in such establishments is to take the material for any given job, at its actual cost, delivered at the factory, including freight, waste, etc., plus the wages actually paid, plus the "burden" on each hour worked by those men in the factory who really produce something. There are, of course, a good many non-producers whose wages go to expense account. This burden is very often put at 20 cents an hour. It may run as low as 15 and as high as 25, but 20 seems to be a somewhat safe average for the ordinary medium-size machine-shop in the United States. A burden rate is ascertained by taking the total expense of running the business, outside of material bought and wages paid. This usually consists of: interest on capital, or, perhaps, rent; insurance; taxes; commercial expenses of selling (the most variable item in the whole account), including advertising, traveling, bad debts, part of office expenses and salaries of officers and clerks, together with many sundries; repairs to machinery and buildings (a very large item); fuel, oil, light and other consumables; wages of non-producers about a factory, as enginemen, janitors, etc., etc.

These items, added up at the end of the year, divided by the total number of hours' work made by the producing class, will give the hourly burden. Of course, it usually comes out in fractional figures, but an approximate rate, in round numbers, is good enough—if set high enough. The burden for each year is based upon the previous one, and hence cannot be really accurate. It will be seen, therefore, that a machine-shop man who uses medium-size tools may very likely find his work costing him 40 cents an hour, 20 cents for wages and 20 cents for expense. In some shops, however, the wages will average 25 or 30 cents, and so the cost may be 45 or 50 cents. Hence, with a not unusual charge of 50 cents an hour, there is a question whether there is a total net profit of as much as 10 per cent.

In using very large machine-tools the average price per hour is put higher because of the greater amount of room these machines take up, and their greater interest and repair account, to say nothing of their likelihood of standing idle more of their time. The machine-shop man, therefore, sometimes perpetrates a charge of \$1.00 an hour, or more.

Hence the outside public who use machines should understand that the profits on making them are not abnormal. They are moderate, and it takes a good deal of time and care to find out what they are, and much good management to keep things going so that the profit comes out on the right side and does not prove to be a minus quantity.

Mr. Foster Crowell said that there is one consideration of this subject which is important: A great many engineers are deterred from an attempt to ascertain the unit prices of the work in their charge, because they think it is a very difficult operation to collect and arrange the data. That is true if the desire is to have an absolutely accurate account which will balance, but, for the purpose in view, it is not necessary that that degree of accuracy should be attained. If such accuracy were to be attempted it would necessitate a duplicate set of accounts, adding much to the cost, and occasioning very great difficulty in getting the accurate data; but it is quite possible to reach a sufficiently close approximation to the cost, and to the average price. Mr. Oberlin Smith spoke of the figures of cost which he had obtained in a given case, and was quite content to express it in terms of an easy average. He did not think it necessary to go down to a decimal of a cent or even to a cent. Now, if engineers in charge of work educate and instruct their staff to collect certain items of information as the work proceeds, it will be found quite easy at the end of the work to approximate the cost of any one of the items, or all the items, with sufficient closeness for comparison and for reference in undertaking other work of the same kind.

The Specific Heat of Steam should be taken about 0.60, instead of 0.48, according to tests of Prof. C. Bach in the Zeitschrift of the Society of German Engineers of May 17.

The Bacterial Treatment of Trades Waste.

Abstract of a paper read before the Institution of Civil Engineers by Mr. William Naylor.

Although much attention has been paid to the treatment of sewage on bacterial filters, little has been heard, up to the present time, concerning the treatment of trades waste in like manner.

The bare fact that in the majority of cases trades waste is likely to be strongly acid or strongly alkaline, or, worse still, charged with chemicals of an antiseptic character, has deterred many from even entertaining the idea of resort to bacterial methods of treatment in connection therewith. The author was induced to pay special attention to the subject by two causes: first, the oft-recurring statement that the sewage of a particular place was difficult to treat because of the admission to the sewers of trades waste; and second, the unexpected behavior of samples of trades waste left standing in unstoppered bottles.

With regard to the first of these considerations, while it must be admitted that in many cases the cost of sewage-treatment is increased by the influx of trades waste, it is only in rare instances that difficulty has occurred in the treatment at outfall-works, such as to call for radical modification of the methods of treatment commonly applied to domestic sewage. Cases within the author's experience are:—Galvanizers' pickle at Wolverhampton, Tipton and Bilston; refuse from tanneries and glove factories at Colne and Yeovil; alkali-waste at Burnley and St. Helens; brewery-waste at Shepton Mallet and Blackburn; woolen-mill and felt-factory waste at Bradford and Nuneaton; bleachworks-waste at Burnley and Horwich. In only two of these cases has any real difficulty arisen.

Examining these kinds of waste more closely, galvanizers' pickle is a common salt of iron, often used as a precipitant for ordinary sewage. It is true it is occasionally accompanied by some free acid, but this only calls for sufficient lime for neutralization in the precipitation-tanks, and the tank-effluent is then normal. At Wolverhampton, during 2 years' observation, the author never discovered a tank-effluent which failed to putrefy on standing, in spite of the fact that the crude sewage contained, in addition, waste and wash-liquors from ammonia and tar-distillation shift-stop liquors, which are generally assumed to have, and probably will have, sterilizing effects in the absence of considerable dilution.

Alkali-waste may be placed in almost the same category as the Black Country waste, for when the sulphides are precipitated by ferric salts the tank-effluent is normal, and the sulphides in the sludge on exposure are almost immediately oxidized. The sewage of St. Helens has recently been treated successfully on bacterial filters. The waste from tanneries and glove-factories may be regarded simply as strong sewage, that from both Colne and Yeovil being quite amenable to bacterial treatment.

Wool-scouring liquors admitted to sewers cause difficulties of a mechanical rather than a bacterial character. Whether these are crude liquors, or the mother-liquors after recovery of grease, a certain amount of fat is included in their burden, and in the latter case some little free acid. If the acid be not neutralized by the soaps natural to the sewage, a little extra lime at the outfall soon settles this matter; but the greater objection is the fat. Quantity is here an important factor, for whereas at Nuneaton the discharges of a greasy nature from fellmongers, hat-works and wool-scourers, are borne by the sewage to the outfall without preventing the production of a satisfactory effluent by ordinary means, at Bradford the character of the sludge formed, which is more or less an emulsion, has hitherto almost defied pressing or handling in any form. At the same time, evidence that the tank-effluent can be treated satisfactorily on bacterial filters is fairly conclusive, and there are no scientific reasons to the contrary.

Bleach-waste and brewery-waste call for special consideration. At this point it will only be said that, whereas at Burnley and at Blackburn bleach-waste and brewery-waste, respectively, is received into the sewers without giving rise to abnormal developments, at Horwich and at Shepton Mallet bleach-waste and brewery-waste, respectively, is admitted to the sewers with disadvantageous consequences, although at the latter two places the ratio of waste to sewage is much greater.

The number of trades-waste samples drawn and examined by the inspecting staff of the Ribble Joint Committee averages fifty per month. After examination many are kept as exhibits. It has been observed that the majority of these, so long as they are not acid, are subject to distinct changes on standing unstoppered. Slightly alkaline samples become neutral; then follows a deposition of coloring matter; and this is succeeded by the growth of either a mold or a green vegetation. The sample filtered from this is clear, sweet-smelling, and lightly charged with dissolved solids. Time and contact with the air being apparently the all-important elements, trials were made with the object of discovering whether these desirable changes could be hastened by artificial means.

A small bacterial filter was constructed, primarily brought into condition by sewage, and provided with a revolving feeding sprinkler; it was found quite practicable to obtain satisfactory results, especially where the waste had been considerably diluted, that is, where the liquors treated consisted largely of wash-waters. Where much free chlorine was present this was not the case; and where, as in print-works waste, color-shop waste, distillery-waste, or strong brewery-waste, starch-products were dealt with, a "souring" took place which very soon impaired the usefulness of the filter. In the last three waste liquors an acid fermentation is set up spontaneously (due largely to the lactic acid ferment) which actually continues during the sprinkling of the filter. It may of course be contended that this particular fermentation is just as much a purification as any other bacterial change, seeing that the result is the disintegration of certain objectionable constituents of the waste. But the time taken for satisfactory purification and clarification while acid fermentation is proceeding is considerable, some of the stronger liquors requiring eight, nine, and even fifteen successive filtrations.

The introduction of competitive and more active organisms—the anaerobic bacteria of putrid sewage—has the effect of preventing the souring almost completely in liquors containing starch or starch-products. A trial of this was first made with ordinary starch. About 20 pounds of starch were mixed with 10 imperial gallons of hot water forming a paste. One-half of this was mixed with 1 imperial gallon of putrid sewage-sludge, and, after having been left standing for 1 day, was examined. After the expiration of 5 days a further sample was examined and then the mixture was passed through the filter. It may be desirable to mention here that, broadly speaking, the products of starch on inversion by acid are dextrose and dextrin; on conversion by diastase, as in brewing-operations, maltose and dextrin; and by spontaneous fermentation a mixture of these products and others, including acids more or less defined.

The dextrose or maltose produced may be measured by the amount of copper oxide reduced, but the dextrin has no reducing-power. As, however, each of the products maltose, dextrose, and dextrin, has a certain optical activity, the amount of dextrin present with either of the other two products can be determined by subtracting the rotary angle due to the quantity of maltose or dextrose present (as measured by means of copper oxide) from the total rotation due to the mixture of the two. The difference in the composition of the mixture after standing 1 day is little more than that due to the dilution or to experimental error. At the expiration of 5 days, however, there is a decided change. The copper oxide reduced amounts to less than one-half, as does also the rotatory angle. This indicates decomposition of the starch to the extent of one-half or more. The remaining portion of the paste, unmixed with sewage, was unchanged in appearance and gave practically the same figures on inversion as on the first day, but smelled offensively.

After passing the mixture, 5 days old, slowly through the filter once, the copper oxide reduced was diminished to less than one-tenth, and the rotatory angle to less than one-half. The albuminoid ammonia—due, of course, to the added sewage—was then estimated for the first time and found to be 0.16 part per 100,000. The liquid was filtered repeatedly up to five times, the operation extending over about 2 working-days.

The other portion of the starch-paste had now become sour and stinking, though otherwise thick, slimy, and gray as at first, and was passed into the filter; but up to the twenty-first filtration a satisfactory effluent was not obtained, and the activity of the filter was impaired if not destroyed. The effluent was turbid, soured on standing, and gave a blue coloration with iodine, indicative of unchanged starch.

About this time, Mr. John Stanning being anxious to improve the condition of the effluent at the Leyland works of the Bleachers' Association the author, on the success of the experiment described above, suggested treating the worst liquors only, in the same manner, and an attempt was made with kier-liquors. These amount to only about 20,000 imperial gallons daily, but as they are produced by boiling raw cloth, first with lime and afterwards with soda, they are very foul and concentrated, apart from the strong alkalinity (nearly one-tenth normal). The most objectionable feature of the waste was its extreme alkalinity. But in spite of the difficulty experienced in preserving the alkalinity of exposed liquors, and knowing the derision with which practical manufacturers would receive a process of impounding, sprinkling, and filtering alkaline liquors for any purpose, and retaining the alkalinity, the trial was proceeded with.

Eight parts of kier-liquor were mixed with one part of wet sewage-sludge and were allowed to stand for 1 week. A reduction in alkalinity was the only noticeable change due to standing. But, after being sprinkled three times over a 3-foot filter of broken clinker, previously brought into condition by sewage, the change was remarkable, the albuminoid ammonia being reduced to nearly one-quarter and the effluent becoming clear and neutral in reaction. The nitrates present were, in the author's experience, phenomenal; due, of course, to the added sewage. The advantage of standing two weeks was found not so considerable as to justify the expenditure involved in the extra tank-accommodation. It is probable that better results would be obtained for less capital expenditure, if more of the outlay was applied to the provision of larger filtering-area.

In view of these results, it was decided to install filters and to modify the tank system for the treatment of the whole volume of liquors, amounting to 500,000 imperial gallons daily; and although, as these are only now in course of construction, no results can be given, those from a similar but smaller installation at a bleach-works and calico-print works—probably the first installation of its kind—can be cited.

The works are those of Messrs. Peel, Tootal & Co., of Baxenden. In these works the processes are uniform from day to day, and consist of boiling gray cotton cloth, first with lime and afterwards with soda. These boilings are followed by an acid wash, and then a chlorine bath, apart from certain intermediate and final washings. The wash-liquor, therefore, contains lime, soda, chlorine, and the various substances removed from the crude cloth (starchy sizes, china-clay, etc), as well as adventitious dirt from the floors and workshops. Some dyeing is also done, and the waste liquors from the dye-becks also find their way to the main outfall.

For some 3 or 4 years before July, 1900, the firm had struggled with precipitation-tanks and ordinary continuous-flow filters without success. At that time proceedings were instituted under the Rivers Pollution Prevention Act, and as a result it was decided to try bacterial treatment. At the outset, the capacity of the tanks was increased so as to be equal to not less than 3 days' flow. The tanks are common impounding-tanks provided with floating arms, and are all connected and used as one large septic tank.

The continuous overflow from the tank runs into a hopper over the revolving sprinkler, which delivers on to a filter of furnace-ashes of graduated size, the largest of which, forming the bottom layer, pass through a 2½-inch ring, and the smallest, forming the top layer, are retained by a ¼-inch mesh. Each filter has an area of 60 square yards and a depth of 11 feet. When the plant was first put into operation, about 4 tons of old sewage-sludge was delivered into the tanks, and they were then filled with ordinary liquors. After standing until the mass became putrid (*i. e.*, for about 4 days), the ordinary liquors were introduced and the filter was fed. To maintain the putridity, all the works-closets were connected with the tanks, and in case of any falling off in that respect, sewage-sludge was added from time to time. This, however, was not found necessary to any considerable extent.

As is the case with all bacterial filters provided with sprinklers, a small amount of suspended matter is delivered with the final effluent, but in this case it is intercepted by a small sand filter.

The working of the plant has been very satisfactory. The effluent is clear and colorless, in spite of the raw liquors varying from a deep purple to a chrome yellow. It is sweet, neutral, contains nitrates and little albuminoid ammonia; and the effect of the antiseptic free chlorine is nowhere observed. The filter is quite active bacterially, and treats successfully 350 gallons per square yard. A further filter is being installed.

The most noticeable feature in the working of the plant at Messrs. Peel, Tootal & Company's works, is that the free chlorine present in the crude waste does not, as might be anticipated, interfere in the least with the bacterial activity of the filter. Presumably it becomes combined in the septic tank with the products of decomposition set free in the putrid sewage. The bleach-waste discharged into the sewers at Horwich is evidently of such volume as to leave a surplus as the tanks are used at present; though it is possible that if they were used on the septic system the difficulty would disappear. At Burnley, bleach-works waste containing no inconsiderable amount of free chlorine is admitted to the sewers, and a satisfactory effluent is obtained from bacterial filters, but the tanks are of open septic type.

Brewery-waste and distillery-waste is treated with difficulty, if at all, on bacterial filters directly, owing to the formation of acids. A sample of crude beer was sprinkled twenty-three times over a bacterial filter 3 feet deep, the loss due to evaporation being continually made up with water; but on each successive filtration the filtrate was sour, and though a considerable change was effected in the liquor, at the conclusion it was of a dark brown color, muddy in appearance, sour and offensive. Another sample was allowed to stand for 5 days in contact with one-fifth of its volume of wet putrid sewage-sludge from a septic tank, and was then sprinkled over and passed through a filter. After the second filtration, both the optical activity and the reducing-power had disappeared, and the fifth filtrate was an excellent effluent showing a diminution in total solids from 3,200 parts to 200 parts per 100,000. The effluent was clear, sweet, colorless and neutral, but contained a small amount of suspended matter. Five filtrations may appear to be an excessive number, but it must be borne in mind that the strength of brewery-waste would be only about one-fifth, and that of distillery-waste about one-half to one-third of the strength of crude beer.

An average distillery may be considered to discharge about the same volume of waste liquors as an average brewery, namely 25,000 to 35,000 imperial gallons daily, and almost any method of treatment applicable to one is applicable to both.

At the Hook Norton Brewery Company's brewery, Hook Norton, Banbury, a settling-tank and continuous-flow sand-and-gravel filter was used, but with little success, during the 6 years ending 1898. It was then tried intermittently with no better result, and on the suggestion of the author the plant was remodeled in 1900. The flow is reduced, by eliminating all clear water, to about 12,000 imperial gallons of strong liquor per day. This is impounded in a settling-tank for not less than 24 hours in contact with putrid sludge from sewage, or 5 per cent. of domestic sewage is admitted to the tank, and when the putridity has once been established, sewage-sludge is no longer necessary. The contents of this tank, which may be termed an "anti-souring" rather than a septic tank, are pumped continually by a pulsometer delivering into the hopper of the sprinkler over the filter. After being first brought into condition by means of sewage only, the filter was started on June 7, 1900. The filter is in better condition than when it was started.

The filtering-medium is coal, screened and graduated in size from about 1-inch cubes at the bottom to ¼-inch cubes at the top. The company, being well provided with steam, were prepared (under threat of legal proceedings from two sources) to pump the first filtrate on to a second filter for further purification, but this was not found necessary. The little suspended matter present after the first filtration is intercepted by shallow sand filters, and the effluent is clear, neutral, colorless, sweet, contains nitrates, and liberates albuminoid ammonia to the extent of about 0.1 part per 100,000. The diminution of dissolved oxygen after saturation, is less than 30 per cent. Similar installations are being made at the Fountains Free Brewery, Blackburn, and, in a modified form, at Messrs. Sumner's Brewery, Haigh, Wigan.

The difficulty with regard to free chlorine having been overcome in the case of bleach dye-works, Messrs. Wiggins, Teape & Co., of Chorley, Lancashire, decided in August, 1900, to try the effect of bacterial treatment on the waste from their paper-mill. The effluent from the mill was fairly clear, having been settled and filtered through continuous filters of animal charcoal. Complaints, however, were made by riparian owners on the River Lostock, some distance below the works, as considerable decomposition took place, with the usual offensive emanations. By this time the sterilizing effects of the chlorine had evidently been annulled. The most objectionable constituent of the crude liquors is the organic matter from the old rags used, and the starchy and fatty sizes from the new unbleached cloth or "parings." It was decided first to try the bacterial filter with sprinklers on the ordinary tank-effluent. Fairly satisfactory results were obtained by this means, but as the effluent was turbid, probably owing to the presence of finely divided particles of china-clay, sewage was added. The installation is practically identical with that at Messrs. Peel, Tootal & Co.'s works, and the Hook Norton brewery. The results are highly satisfactory—one of them, of no little importance, being the absence of the turbidity due to the coagulating effect of the sewage. In almost all mills where esparto grass is used, much difficulty is experienced in obtaining a clear effluent, even after filtration through very fine ashes. After admixture with sewage, however, and sprinkling, the final effluent contains much less suspended matter than that from brewery-waste.

In the discussion of the paper, Dr. Samuel Rideal stated that the author had confirmed the view which he himself held, that if the proper sequence of bacterial processes was adopted, practically all kinds of organic matter would break down and give satisfactory effluents. By proper sequence he meant, not the method adopted 5 or 6 years ago, following the work of the Massachusetts Board of Health, of attempting to effect the whole decomposition in a contact-bed, but the realization of the absolute necessity of bringing about a preliminary decomposition of an anaerobic character before passing the liquid into a filter-bed where it was under oxidizing influences. With regard to the starch-paste experiments, all chemists were well aware that complex carbohydrates were capable of being broken down into carbohydrates of simpler constitution by a process of hydrolysis which did not involve any oxidation at all. But that inversion or hydrolysis required time and suitable conditions, and one of those conditions was not the presence of oxygen. It was seen clearly from the experiments in the paper that the cellulose liquids which had caused a great deal of nuisance in many districts when allowed to stand by themselves with the proper ferment, produced by mixing them with some anaerobic sewage, underwent a considerable breaking down into these simpler carbohydrates, which were then easily oxidized in the final stage. Another point brought out clearly was that the effect of the decomposing-tank or preliminary anaerobic decomposition was sometimes to augment very considerably a figure by which both engineers and chemists in the past had set great store, namely, the albuminoid ammonia. Therefore, as he had contended on previous occasions, an arbitrary standard of albuminoid ammonia must not be set up, because here was a process going on in the direction of purification, but involving in every one of the experiments an increase in the albuminoid ammonia. Another point of interest was the possibility of dealing, by bacterial action, with liquids containing chlorine. He had studied some of the electrolytic processes, and had found that chlorine had a marked sterilizing effect only when the organic matter had been practically removed by some preliminary bacterial process; and then very good sterilization could be produced. Bacterial treatment was therefore consistent with the presence of chlorine in those cases in which this absorption of free chlorine by some of the organic matter first took place. Free chlorine was also removed in another way prior to bacterial decomposition—he thought it had been so removed in some of the author's experiments—namely, in the presence of ammonia. Free ammonia re-acted with chlorine very quickly, a neutralization was effected, and the germicidal properties of the free chlorine were in this way removed. Therefore a liquid containing free ammonia as well as free chlorine quickly reached a state in which it was amenable to bacterial change.

Engine Governing and Parallel Running of Alternators.

Some time ago the International Society of Electrical Engineers appointed a committee consisting of Messrs. Blondel, Rateau, Miet, Guilhert, van der Stegen, Picou, Vigreux, Brillié and Chevrier to investigate the whole question of the parallel running of alternators as affected by engine governors. Their report was given out late last spring, and the following abstract of its contents has been published by "Science Abstracts:"

The desirability is shown of defining by a special coefficient $K = (N_o - N_{max})/N_o$, (N_o and N_{max} = angular velocities at no load and full load respectively) the controlling power of the governor. This coefficient, or some other similar function of the speeds, has been called the coefficient of isochronism. Inasmuch, however, as isochronism is a most undesirable condition for parallel running, the term is inappropriate, and "governor coefficient" is proposed as a better name. The curve representing mean angular speeds as a function of the load is of great importance; this is really the mean between two nearly parallel curves, the difference of whose ordinates is called the stability; the actual mean speed for any load may oscillate between the two limits, this oscillation being due, amongst other things, to variations in friction and to play in bearings and gear-teeth. For a given load the "stability" of the governor ought, for reasons which are explained, to be greater than the difference between the maximum and minimum instantaneous speeds during one revolution. It is shown that, for the same stability, the loads taken by different sets (supposed of equal capacity) will tend towards equality as the curves referred to are more inclined towards the axis of load.

Various engine-makers and central station engineers were asked to obtain experimentally curves of mean engine speed as a function of load, some of which are reproduced. Pressure in the steam chests, in one typical case, was maintained constant by means of the throttle valve; the curve is nearly a straight line, slightly convex to the origin. The drop is about 5 per cent. between no load and full, the load being that between the alternator terminals. If indicated horse power is plotted as abscissa, the convexity is increased. It is desirable, but not absolutely necessary, that the drop in speed should be proportional to the load; the possible difference in the load taken by two identical sets in parallel is then constant for all loads. The form of curve giving a difference of load proportional to the load is that which is convex to the origin; curves with a point of inflexion and a tangent nearly horizontal are quite impossible for satisfactory parallel running.

The necessity for a considerable "governor coefficient" for parallel working necessitates a special compensation arrangement to maintain the frequency constant. Three such devices are described. One consists of a weight movable either by hand or from the switchboard by means of a small electromotor, which varies the effort which the governor must exert in order to come into action; or the effect of the weight may be altered without the necessity for displacing it, by means of the current in a solenoid. The second way is to act on the admission valve of the engine so as to vary the pressure at the steam ports as the load varies. The ...rd method is to use some automatic regulator, such as the Denis compensator, employed by some engine-builders in Paris. The two first methods, while giving the necessary variation of speed, are not always sufficient to maintain it constant; in such a case, a method devised by Picou has been used, by which a by-pass with an easily regulated valve is used to shunt the steam admitted to a cylinder.

What is the best type of governor? Theoretically any form of governor can give a required percentage drop, but practical considerations of dimensions may make one system preferable to another. Quick-acting governors, in which centrifugal force is counterbalanced by springs, are best for parallel running; the possibility of modifying the range, etc., when in place is also an important consideration; and spring governors or those which make use of an inclined plane lend themselves easily to this.

Governor oscillations. The period of these ought not to coincide with the period of oscillation of the flywheel, if dangerous hunting is to be avoided. With spring governors the period is generally very short, and can easily be calculated.

Method of damping oscillations. Short-period oscillations, such as, e.g., those depending solely on the governor, can be damped by a dashpot; the damping need not be considerable, as friction alone will do nearly all that is required. Long-period oscillations require very powerful damping; but here a curious effect comes in, that if the orifices in the dashpot piston are adjusted to give the best effect for oscillations of long period, the resulting damping for short-period oscillations will be exaggerated. A remedy for this is to have a dashpot provided with valves which relieve the pressure of the oil when this exceeds a certain limit.

Governors ought to he of short-period of oscillation, and, to avoid resonance, the various oscillation periods of the plant ought to be different.

The influence of multiple expansion on governor oscillations. When, as is generally the case, the governor controls the admission to the high-pressure cylinder only, its rapidity of action is diminished by multiple expansion—a condition prejudicial to good parallel working; and the tendency to oscillations is also increased. When the governor acts on the different cylinders, this tendency is less marked.

Oscillations of long period. These are given rise to by variation in the existing torque under certain states of load and by somewhat undefined conditions of the governor, particularly excessive damping. In the case of two alternators in parallel, they can be produced by a want of balance of power between the two machines owing to lack of simultaneity in the action of the governors. Long-period oscillations can be reduced (1) by increasing the "governor coefficient," (2) by reducing the distance between the two limiting curves which represent mean speed as a function of load, and (3) by increasing the power of the governor. If the alternator drives the engine, however, these oscillations may reappear.

The best way of governing several alternators running in parallel. Should each set have its own governor, as is the usual practice, or would it be better to regulate the speed of the whole system by a single governor (a) acting either on one only of the engines, the governors of the others only serving in case of accident, or (b) acting simultaneously on the admission of all the engines? The first method (each plant separately governed) demands that the governors should be very sensitive and should have practically the same percentage drop at full load; but in practice it is found possible even with different types of governors to obtain satisfactory results. The disadvantage of this method is that the load comes on or off all the machines simultaneously. Rateau proposes to use governors with large percentage drop in combination with Denis compensators; these would be adjusted for the different machines to speeds varying slightly the one from the other. Thus, in the case of four machines running at a speed of about 100, the compensators might be set at 102, 101, 100 and 99 revolutions respectively. Thus there would never under normal conditions be more than one machine running at reduced load; the others would be either fully loaded, or would be taking no load and would of course then be shut down. The second solution (one governor controlling the whole of the alternators running in parallel by regulating the admission of its own engine) may do well enough where the variation is small as on lightning circuits. Where, however, the variations might exceed the capacity of the controlling machine, serious dangers might be introduced. Against this there is the great advantage that all the other sets are acting under the best conditions economically. With asynchronous alternators this method would be the natural one to employ, if the control were effected by a synchronous alternator. The third method, while electrically leaving little to be desired, is mechanically very difficult to realize.

The Manchester Ship Canal Company had an unusually prosperous career during the first half of this year, according to the report to the stockholders by Chairman J. K. Bythell. The receipts showed an increase over the preceding half year's figures of $97,600, while the increase in the expenditures was but $8,100. The sea-borne imports and exports amount to 1,457,000 tons, an increase of 195,000 tons over the amount for the preceding six months. A number of new steamship lines running to Manchester have been established, although the season generally has been very dull in British shipping circles.

The Power Plant of the Highland Canal & Power Company, on which construction has just begun, is to have an original installation of 30,000 horse-power for use in Duluth and on the Masaba range. The water-shed is about 2,500 square miles with an average annual rainfall of 30 inches; the reservoir capacity will be one-fifth the annual precipitation. From the reservoir system a 2½-mile canal will run to a so-called forebay with an area of 1 square mile and an average depth of 20 feet. From this two lines of 72-inch riveted steel pipe will run to the power house 10,000 feet distant, on Duluth Harbor, where the effective head will be about 660 feet. Each of the six units will have two Pelton wheels direct-connected to a generator furnishing 5,000 electrical horse-power at 220 revolutions per minute. Three-phase current at 25 cycles and 6,600 volts will be furnished. An auxiliary receiver or equalizer has been connected with all the pipe lines and with each unit in the power house. This arrangement, coupled with relief valves, is expected by Mr. F. A. Cokefair, chief engineer, to insure safety against damage by water-ram, reduce the friction loss in pipes by keeping the velocity constant in all and allow the operation of any unit from the receiver in case of repairs to the pipe lines.

The Paradox of the Pantheon.

The Romans were the first people to realize the artistic value and develop the architectural possibilities of the groined vault and dome. By their means they obtained effects of unencumbered spaciousness impossible with columns and piers. Greek buildings remain to our day only as roofless ruins. The stupendous monuments of Egypt, rivalling those of Rome in magnitude, are chiefly open courts and colonnades with hypostyle halls, which, though roofed with stone, are encumbered by columns. In the Great Hall at Karnak, the broadest aisle is less than 20 feet wide in the clear and not over 80 feet high. In contrast with these dimensions are those of the Baths of Diocletian at Rome, which have an unencumbered floor space of 340x87 feet with a groined vault 90 feet high. The constructive methods by which the Romans accomplished the erection of these great buildings have been investigated by many architects and are the subject of several valuable books. A systematic study and examination of Roman vaulting has never been undertaken, however, and in the most perfectly preserved and frequently visited of all Roman monuments, the Pantheon, the extraordinary contradiction between the construction and decoration of the magnificent dome, though known for 150 years, has hardly been discussed. In 1894 Prof. A. D. F. Hamlin, of Columbia University, observed certain facts which suggested a surprising explanation of this paradox, and after waiting in vain for some years for a solution from some other source, has discussed the subject in a series of papers in the "School of Mines Quarterly," from which the following notes have been abridged with his permission. As a study in ancient Roman vault construction, apart from the Pantheon problem, the papers also merit the attention of all interested in the engineering and architectural methods of bygone days.

The true Roman system of construction is particularly interesting at the present time because it was based on the use of concrete. The architecture of the Egyptians and the Greeks was one of stone, and the construction of their great edifices was a tedious labor. When Rome, enriched by the spoils of world-wide conquests, began to build on a grand scale, the slow processes of stone construction were out of the question. She had enormous resources as respects rude labor, and the practical Roman builders accordingly devised a system of construction utilizing this unskilled labor to the utmost, employing the relatively limited artistic resources of the empire so as to make a minimum of original design serve for a maximum of buildings. Hence the greater part of the walls, piers and vaults were concrete, and brick and stone were used only for facings.

The builders were economical in many respects. To support the enormous weight of the heavy concrete vaulting while it was setting would have involved a massiveness of timber construction for centerings which was deemed extravagant, and two other methods were adopted to accomplish the same end. Sometimes, over a very light wooden frame covered with slats a couple of feet apart, there was built a thin vault of large flat tiles laid in strong cement. These were covered in turn with smaller tiles breaking joints with the layer below. This made a strong elastic shell, which, when loaded up to the haunches with concrete, was quite sufficient to carry the load of the concrete afterwards placed on the upper portion to complete the vault. The second method of construction, used in the larger vaults, was more complex. Cellular ribs of brick and tile were first built on light centers. Other centers were then fixed between the ribs and the intervening space was filled with concrete. As these fillings, starting from the spring and growing a foot or two daily, hardened, they formed monolithic lintels between the ribs, bracing them against lateral overturning and taking upon themselves a part of the weight of the next portion of the filling.

It is noteworthy that these admirable building methods eventually degenerated into matters of unthinking routine, and there are ribbed vaults where the ribs could have served no useful purpose. Even the Pantheon, dating from the early part of the second century, is full of solecisms. Lanciani declares that the beautifully executed discharging arches which are so noticeable in the upper part of the exterior brick facing are only one brick deep and serve no constructive purpose. In the dome of this building the constructive ingenuity of the Romans appears highly developed and yet associated with the most extraordinary disregard alike of that economy of means and labor which characterizes many phases of Roman building and of the logical connection which in most great architectural works exists between the structural framework and the decorative dress. In the dome of the Pantheon these are not merely independent but are absolutely contradictory.

The Pantheon was built by Hadrian between 117 and 138 on the site of an earlier temple constructed by Agrippa. The portico is a reconstruction by Septimius Severus and Caracalla with materials from an older structure. The building is a circular edifice 142 feet in diameter, internally covered by a hemispherical dome 140 feet high, springing from the circular wall. This wall is 20 feet thick, but its seeming massiveness is reduced one-half by seven niches, n, Figure 1, opening inwards and alternately rectangular and semi-circular in plan, an eighth opening forming the great doorway; and eight smaller semi-circular chambers, opening outward only through small windows. The eight large niches are capped by arches and half-domes. The wall appears to have been constructed in the usual way with facing of broad flat bricks and a filling of pozzolana concrete. The dome is sprung low enough to be inscribed within the square of 142 feet. The 28-foot oculus or eye at the summit not only lights the interior in the most beautiful manner imaginable, but relieves the dome of a great weight at its weakest point; while the carrying up of the exterior drum to one-third the height of the dome, and the series of external steps encircling the dome above it, provide for the loading of the haunches of the vault in the most satisfactory way.

Very effective, also, and admirably simple is the interior paneling of the dome with 140 plain rectangular coffers, each showing four sinkages except in the panels of the upper or fifth tier, which have but three. The lower rails in each panel are wider than the upper ones in order to render them visible to a spectator on the floor of the temple. The paradox of the Pantheon is to be found in this interior paneled face of the vault.

The use of panels as a ceiling decoration lent itself readily to Roman methods of vaulting with brick ribs, which could be arranged to form the vertical members of the framework of the panels, while the horizontal members or rails could likewise be built of brick, forming a rectangular network of bricks sufficiently rigid when set to carry of itself the concrete filling and backing of the vault. But as a matter of fact few large vaults remain which show this system of construction. The great vault of Diocletian's baths, now the church of S. Maria degli Angeli, is quite smooth and plain internally. Others, like the vaults of the side chambers of the Basilica of Maxentius and Constantine, are adorned with polygonal panels, large octagons and small squares or other like combinations, which contradict any practical system of structural ribs. The one complete and monumental example of this kind of vault decoration is the Pantheon, and here, if anywhere, it would seem to be the natural thing to allow the ribbing of the vault panels to dictate the design of the structural framework of the dome. The interior aspect of the dome would naturally suggest a system of vertical ribs converging to the oculus, and a series of horizontal arches between them, framing the panels and stiffening the whole skeleton. But this is not at all the way the dome was constructed, and unfortunately it is impossible at present to say clearly how it was built.

The discordance between the lines of the paneling and the structural skeleton of the dome was first observed during repairs executed between 1743 and 1756, when an architect named Piranesi was enabled to study the construction. His drawings, Figure 2, stated to be from measurements, show a framework of eight discharging arches over the eight niches or chapels, supporting eight massive ribs springing from their crowns and braced against disruption under this heavy load by a second tier of arches sprung from the haunches. This system of arches and ribs, harmonizing with the general plan of the wall below, was generally accepted by students of Roman art until recently. The fact that its lines cut across those of the panels and that an eight-fold system is fundamentally inharmonious with one of twenty-eight parts, was of course patent to the most careless observer. But this did not discredit Piranesi's presentation of the structural framework of the dome, because this, if inharmonious with the paneling, was perfectly consistent with the eight-part design of the whole interior, and the paneling was generally considered as a decorative appliqué of ribs in relief, presumably in concrete or stucco, on the inner surface of the completed vault, as shown in Piranesi's cross-sections.

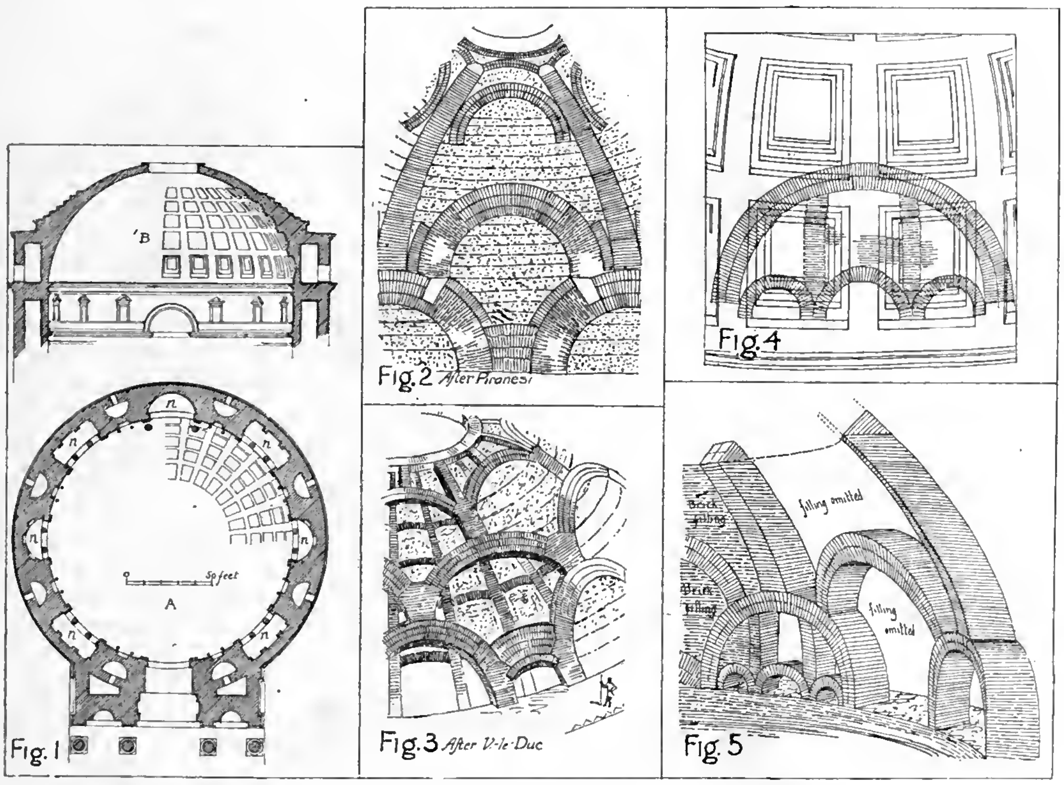
This explanation of the construction of the dome was questioned by Viollet-le-Duc in his famous "Dictionnaire." He suggested Figure 3, a preliminary skeleton of twenty-eight ribs and four series of horizontal arches, all of brick, light enough to be carried by trussed centerings; these formed the paneled design of the inner surface of the dome and served as a permanent centering for the construction of a more massive outer shell of arches and ribs after a modification of Piranesi's system. But this was merely a clever speculation of the French architect and has no basis in observed facts.

Professor Josef Durm, in his "Baukunst der Römer," discredits Piranesi's scheme by claiming that the latter could have discovered the ribs and arches only by cutting through the exterior cornice and steps around the base and haunches of the dome, and that, as there is no evidence of this, "one may be led to the conclusion that Piranesi was entertaining his readers with a figment of his own imagination." Durm accepts, however, the theory of two shells and two superposed frameworks, but he suggests that there are fourteen and not eight ribs, and that they are sprung directly from the wall and not from discharging arches. He seems to have overlooked the fact that in harmonizing the framing and paneling, he has thrown the framing and the walls supporting it out of accord. Moreover it hardly seems likely that Piranesi would entirely invent his system at a time when the evidences of his fraud would be so entirely patent to other observers.

From a study of these data and theories, which he gives more completely in his papers, Professor Hamlin reached the conclusion that Viollet-le-Duc's assumption of two shells was reasonable, although without insisting on the order in which they were built. It was possible that the outer or Piranesi shell was built first and the paneled framework laid up afterwards, on the removal of the great centerings for the outer shell, by means of movable centerings hung from the outer framework. Each zone of the paneling would be self-sustaining as soon as completed. If thus constructed as an afterthought, perhaps when Septimius Severus rebuilt the portion, its discordance with the divisions of the dome framework is easier to understand. It was with this theory in mind that Professor Hamlin examined the dome in 1894. Two years earlier, M. Chédanne had removed the stucco from three panels of the lower row in the dome and from several small areas near these. These bare spots were examined with an opera glass, as there was no scaffolding from which a close examination could be made at the time, and it was clearly seen that the whole structure was brick, ribs and filling alike. But the singular fact became apparent that it was not composed of structural ribs laid up as such according to the theories of Viollet-le-Duc and Durm, but the paneling was formed in the substance of the massive dome of brick, with discharging arches cutting at haphazard across the panels, as shown in Figure 4. The theory of a double shell, as well as that of paneling in concrete added as an afterthought, was thus disposed of. The dome was a single massive vault of solid brick, an unusual construction in Rome; the paneling was formed in the brickwork itself and this brickwork was laid up in a series of discharging arches, for a part of its height at least. These were plainly seen to have been planned with reference to the chapels or niches below, and so far, at least, Piranesi was proved to have been correct.

But these facts merely shifted the puzzle, they did not solve it. The inherent contradiction between the twenty-eight panel ribs and the eight-fold design of the rotunda was not explained, it was accentuated. The 140 panels were a part of the dome itself. The only explanation of the contradiction, to the satisfaction of Prof. Hamlin, is that the paneling was a decorative embellishment of the dome, which was originally intended to present a smooth internal surface, and that the panels were hewn in the solid brickwork after the completion of the vault. Prof. Hamlin acknowledges that such a procedure is contrary to the assumed method of Roman construction; but the alternative solution, that the panels were formed during the laying up of the various discharging arches, assumes the use of molds and of complicated special shapes of brick far exceeding the capabilities of Roman masons at the time this work was done. In Professor Hamlin's papers he explains in detail the intricacy of the mason work necessary in laying up the relieving arches and their filling over the huge forms for the panels.

If the dome is supposed to have been built first, with or without a skeleton of arches and structural ribs extending through its whole thickness, and without regard to interior decoration, it becomes clear that this could be done with relatively light and simple trussed centerings. Chédanne has shown from his examination of the brickwork that the eight discharging arches are built like vertical arches, although with the inner faces shaped to the curve of the dome. If this is also true of a second row of arches, as in the Piranesi theory, all the lower part of the dome could have been built up nearly to half its height without centering. As a matter of fact, Piranesi's sections show all the masonry of the dome up to the level of the fourth row of panels laid up in horizontal courses, and with this Chédanne's observations agree. From that level, it was possible to erect the eight massive ribs and the oculus at the top on skeleton centerings, spanning the opening with trusses either resting on the completed zone or supported from the floor of the rotunda. In Figure 5 Professor Hamlin sketches a part of the dome carried up in this manner; he does not claim that this was done, but merely suggests that such a procedure was possible and comparatively simple if the builders did not concern themselves about the interior paneling. The dome being completed and the centerings removed, wholly or in part, the hewing of the panels subsequently would be a simple matter without endangering the stability of the vault. The work would be simple, within the ability of laborers of little or no skill, and remarkable only for its quantity and not its difficulty. That the panels were formed in this manner is the more credible because it allows the supposition that the interior decoration was designed quite independently of the construction.



PROFESSOR HAMLIN'S SKETCHES OF THE DOME OF THE PANTHEON.

But two objections have been advanced against the validity of this theory. Chédanne has reported that the surface of the bricks does not indicate cutting. But Professor Hamlin finds it easier to believe Chédanne mistaken in his observations on this point than to suppose the arches could have been built into the molds without cutting or breaking the bricks; in most cases, he states, it would have been an absolute impossibility. On the other hand, the rough hewing of the panels, to be finished afterwards in stucco, might in many places have exposed such a serrated surface as Chédanne appears to have noticed, where the ends of brick came close to the hewing line.

The other argument is the fact that in the center of each panel there is a bronze anchor set in the brickwork to hold a bronze rosette or other ornament. It is not impossible that these were set in the brickwork after its completion, as such an operation is common enough in modern work. But even were this not so, it would simply prove that the paneling had been conceived and provided for when the dome was first built, without at all proving that the panels were actually shaped in the extremely difficult manner suggested by M. Chédanne.

Evidence of the most valuable nature as to the merits of these various explanations of the paradox of the Pantheon could be drawn from the appearance of other buildings of like character, but the present state of knowledge of the details of the vaults from the time of Hadrian to that of Constantine is inconclusive. Only by a critical examination of these structures can the true history and chronology of paneled vault decoration be worked out. Professor Hamlin gives illustrations of a few examples of such paneled vaulting in which the work is considered to support his theories. The summary of his investigations and studies he states in the following words.

"To sum up the conclusions which appear most rational, taking into account the present unsatisfactory character of the evidence at hand, or at least its lack of final conclusiveness, it would seem probable that the dome of the Pantheon as constructed in the time of Hadrian was internally a smooth vault, as its upper part always remained, and as many great vaults often were, *e. g.*, the great vault of the Tepidarium of Diocletian's Baths, now the nave of S. Maria degli Angeli. At some date subsequent to its completion, and very probably in the time of Septimius Severus, who rebuilt the great portico of the temple, or of Caracalla, it would appear that the emperor, desiring to embellish the dome and to replace its faded or ineffective stucco decoration with something more permanent and dignified, caused the existing panels to be hewn as a part of his work of general restoration and improvement. Owing to the difficulty and danger of working from overhead in the nearly flat central field of the dome, this work was confined to the lower three-quarters of its surface. It was a work easily executed when once the scaffolding was erected. No indications of the internal structure, discharging-arches or ribs appeared upon the stuccoed surface of the dome. The designer concerned himself, therefore, with only two problems—to secure an adequate scale in his work and to arrange so that the panels should center over the four axial niches of the building. The resultant of these two considerations was the adoption of a scale or spacing giving six panels intermediate between those centered on the axes of the building. The panels were marked out on the plastered surface and the cutting begun, the hewing away of portions of the discharging-arches of the dome being a relatively unimportant incident of the work. The beveling of the lower reveal of each sinkage of the panels was a very simple detail of the cutting, although it would have caused infinite labor and trouble to execute upon a mould as suggested by M. Chédanne. When the hewing was thus completed the whole was once more stuccoed, mouldings were run in the stucco of the edges of the 140 panels, the central rosettes and adornments of gilded bronze were added and the work was completed.

"The final proof or disproof of this theory must rest upon further and more minute investigation than has yet been possible, both of the Pantheon itself—to the unraveling of whose complicated history M. Chédanne has made so important a contribution—and of other vaulted structures of the Roman Imperial epoch. The Piranesi system must be finally vindicated or disproved by a more complete examination of the dome than has so far been undertaken. The brickwork of this and other monuments must be examined for technical evidence as to its having been hewn or laid up to a mold. It is to be hoped that the labors of the Italian government, whose Direzione Generale delle Antichità watches with such zealous and intelligent guardianship over its priceless archæological possessions, and the investigations of archæologists and students, both Italian and foreign, to whom the government shows such considerate hospitality, may at no distant date finally and authoritatively elucidate the paradox of the Pantheon."

Ventilating and Heating No. 23 School, Rochester, N. Y.

An interesting example of schoolhouse planning and schoolhouse heating and ventilation is afforded in a recently completed school building in Rochester, N. Y., No. 23, on Bowen Street in the eastern part of that city. These structures in Rochester, have for some time been designed by Mr. J. Foster Warner, of Rochester, and the present instance may be presented as typical of Rochester schoolhouse practice. No. 23 school is a two-story building comprising 16 grade rooms, all approximately of the same size, 24x30 feet, a kindergarten, one recitation room, a library, teachers' and a principal room and a large assembly room, besides the various utility rooms and some spaces in the basement. The fan system of heating has been installed for ventilation with direct steam radiation in the rooms for warming. The building complete, enclosing in the two stories 345,000 cubic feet of space, cost, including the heating and ventilating apparatus, $58,000.

An idea of the general arrangement of the rooms and the scheme for heating and ventilation can be obtained from the accompanying plans, which comprise a basement plan, half plans of the first and attic stories and various details. The building has extreme dimensions of 103x185 feet. It stands 100 feet back from Bowen Street on a lot extending through to another street and large enough for the exterior to appear to advantage. Its main entrance is in the center of the front facade and there are two pupils' entrances, one at each end of the building. Each school room is provided with its corresponding wardrobe, as shown, and is reached either directly from the corridor or from the wardrobe. Toilet rooms are provided on both the first and second floors, in ready access to the rooms served. The assembly room is located in the rear central part of the building at a lower level than the first floor, with two exits at the rear at ground level. It is about 58x58 feet in plan and separated with drop sliding doors from the main corridor of the first floor, which can thus be utilized as a gallery. In this connection mention may be made of foot warmers which are provided in the corridors. These are two in number and are not of the indirect type but consist of a direct radiating steam coil, set in a tin-lined recess in the first floor, the recess covered with a plain japanned iron lattice-pattern register. The register is about 10 feet long and a seat has been built alongside it its full length.

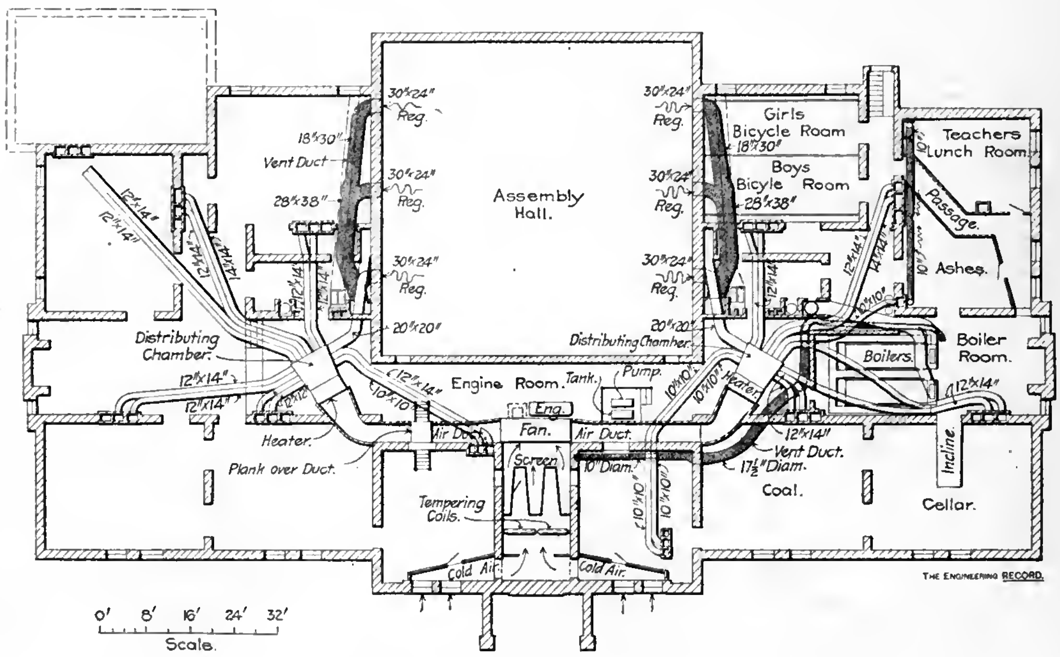
The second story is similar in arrangement to the first story, except, of course, that the assembly room does not continue through it. A recitation room, 18.5x24.5 feet is located in this story, serving the higher grade classes. In order to insulate it so far as possible against sound transfers into adjoining rooms, its walls enclose airspaces. These inside walls of the room are supported on 2x4 inch timbers staggered to leave about 5 inches air space between the inner wall surfaces, which consist of Neponset red rope paper tacked to wood cleats attached to the 2x4-inch timbers. The basement contains only general cellar and the heating apparatus, two bicycle rooms and a teachers' lunch room.

The ventilating apparatus is symmetrically arranged about the center line of the building and consists of an engine-driven double discharge blower which forces tempered air to two distributing points where heaters are installed and the individual supplies to the various rooms are taken. The air is received during school sessions through basement windows in the front of the building, passes through the tempering coil and thence to the fan through a cheese cloth screen for removing dust. The inner walls of the cold-air chambers, it will be noticed, are fitted with sashes of window glass to afford light to the spaces behind them. The tempering coil consists of four 5-foot sections of Sturtevant pipe coil heaters, two sections with four rows of 1-inch pipe and the other with two rows, and all 29 rows long standing 9 feet high. Altogether there are 2,550 feet of pipe, or 850 square feet of surface. These coils are provided with a bypass damper controlled by a Johnson thermostat in the tempered air chamber.

The blower is a 9x4.5-foot three-quarter housing Sturtevant fan driven by a directly-connected 15x10-inch center-crank horizontal Sturtevant engine. The engine is designed to drive the fan at a maximum speed of 150 revolutions per minute at 25 pounds maximum steam pressure and the system is calculated to deliver to each of 19 school and one recitation room, including two rooms of a future addition, 1,200 cubic feet of air per minute, to the assembly hall 8,000 cubic feet of air per minute, and suitable amounts to the principal's room, the library and the teachers' room, all at the same time. This amounts to something over 32,000 cubic feet of air per minute and gives a velocity of flow through the passages from the cold-air inlet to the fan of about 250 feet per minute and through the cheese cloth filter, which presents about 450 square feet of surface of 70 feet per minute.

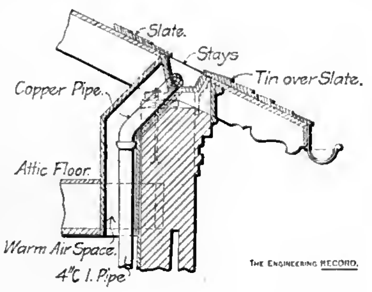
The air is discharged in opposite directions from the fan to two distributing chambers, at the entrance of each of which the main heater for each half of the building is placed. These are of the same type as the tempering coils, each containing about 3,763 lineal feet of 1-inch pipe, or 1,254 square feet of surface. Each heater comprises four sections, 6 feet 4 inches long, with four rows of pipes, each with 35 pipes 8 feet high. The heaters are also provided with by-passes underneath and at the distributing chamber, where, as stated, the individual room supplies are taken, butterfly mixing dampers, under the control of Johnson thermostats placed in the rooms corresponding, regulate the mixture of tempered and heated air to suit the local room conditions.

The air is delivered to the rooms at the usual height of about 8 feet through bronze screens made of flat crimped iron of plain



Foundation Plan, Showing Ventilating System.

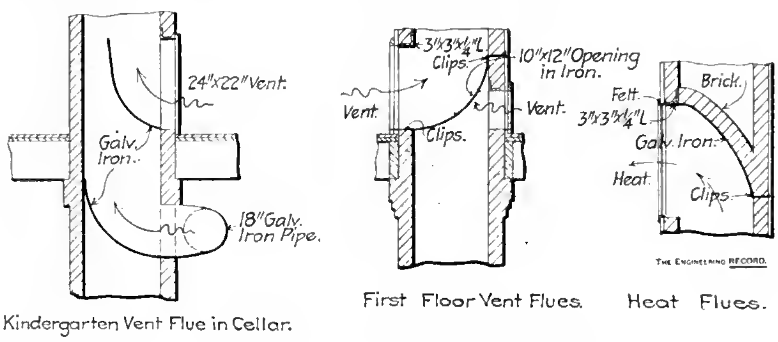
lattice pattern, set in an angle-iron frame. As already stated, the ventilating system is based on the supply of 1,200 cubic feet of air per minute to the average room, which on the basis of 30 cubic feet of air per capita per minute, allows for 40 pupils per room. The rooms being 24x30 feet in size, the gross amount of floor space per pupil is thus 18 square feet. The air supply to each room is carried from the distributing chamber in a 12x14-inch horizontal galvanized-iron duct and in a brick flue 20x24 inches in cross-section. The velocity of the air in the former case is accordingly 1,000 feet per minute and in the



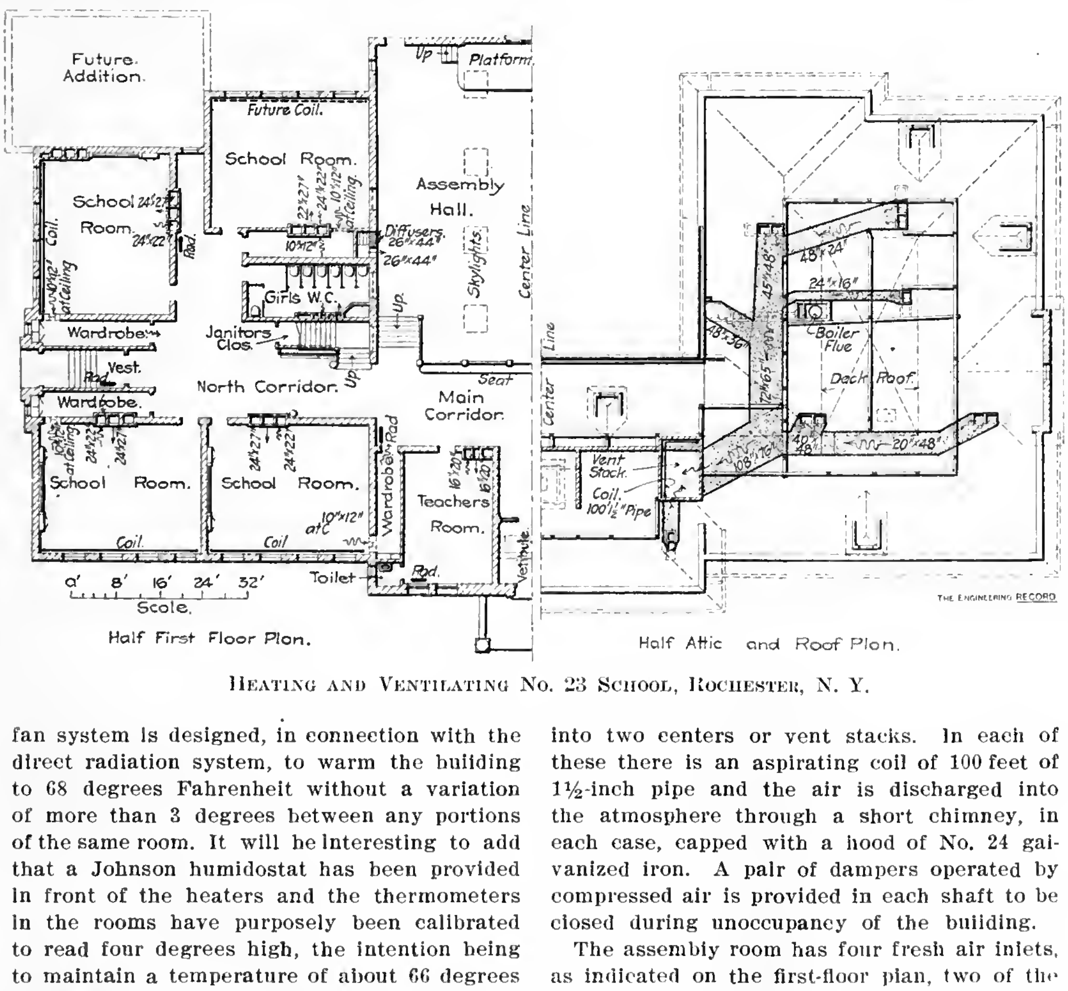
Section of Box Gutter and Cornice of Conductor.

latter 360 feet per minute. The register areas are 24x27 inches, so that the register is about 1 1/3 times the size of the flue. Allowing for lattice work, the velocity through the registers is about 350 feet per minute.

The flues are unlined, the brick work being rubbed smooth, but at bottom and top galvanized-iron is used to break the right angle turn and avoid eddying of the air. The construction at the top of the heat flues is shown in an accompanying detail drawing. The brickwork is arched over behind the galvanized-iron work. The inside of all flues visible through the registers are colored with red water paint. The



DETAILS OF FLUE CONSTRUCTION.



HEATING AND VENTILATING NO. 23 SCHOOL, ROCHESTER, N. Y.

fan system is designed, in connection with the direct radiation system, to warm the building to 68 degrees Fahrenheit without a variation of more than 3 degrees between any portions of the same room. It will be interesting to add that a Johnson humidostat has been provided in front of the heaters and the thermometers in the rooms have purposely been calibrated to read four degrees high, the intention being to maintain a temperature of about 66 degrees and a humidity of 50 per cent., without alarming the teacher by a thermometer reading below 70 degrees.

The outflow of air from the rooms is accomplished in general through two passages, through a vent register at the floor opening into a flue adjoining the hot-air flue and through a vent register at the ceiling over the door to the wardrobe, the area of these two registers aggregating that of the fresh air register. This latter arrangement provides for the ventilation of the wardrobes, which are fitted with hooks fastened to a cleat which extends six inches from the side walls, and with a small cupboard which has a galvanized wire panel affording a circulation of air. The air from the wardrobes passes into the vent flue that serves the school room, except in a number of cases where the location of the wardrobe did not allow of this arrangement, the latter instance having, for example, in the first story, floor registers admitting the air to a system of vent ducts in the basement. This system, as shown in the basement plan, is connected with the space surrounding the smoke stack, and the air in that way is given the accelerating force of the heat from the boiler flue. An accompanying cross-section shows the base of the vent flue and the opening to allow the passage of air from the wardrobe. At the attic, as shown, the exhaust air is collected by ducts into two centers or vent stacks. In each of these there is an aspirating coil of 100 feet of 1½-inch pipe and the air is discharged into the atmosphere through a short chimney, in each case, capped with a hood of No. 24 galvanized iron. A pair of dampers operated by compressed air is provided in each shaft to be closed during unoccupancy of the building.

The assembly room has four fresh air inlets, as indicated on the first-floor plan, two of the openings allowing the air to issue toward the center of the room and the others fitted with deflectors to direct the air toward the outer end of the room, where it was not so convenient to locate fresh air passages. In each case the supply duct for this room has a blast gate near the distributing chamber. The air is exhausted at the floor line with three side registers alongside each side wall, the aggregate area of the six vent registers being about 1.9 times that of the fresh air registers. Ducts in the basement carry the air to two large vent shafts, which lead to the attic, where the air is collected and discharged, as described.

The toilet rooms are ventilated independently of the rest of the building. Each is warmed by indirect radiation with stacks in the basement through which is conducted fresh air from independent air inlets in the rear basement wall. The stacks are located high enough to drain directly into the boilers by gravity, so that they can be operated at any time without regard to boiler pressure. Each stack has about 60 square feet of surface. The vitiated air from the toilet rooms is carried upward and discharged through separate flues into the atmosphere.

Steam for the plant is generated in horizontal tubular boilers, installed in duplicate. They were built by Atlas Engine Works, to stand 100 pounds pressure, but the maximum working pressure is intended not to exceed 25 pounds. Each boiler has a 54-inch shell with 46 tubes 3½ inches in diameter and 14 feet long. The main steam supply is 6 inches in diameter subdivided into a 3-inch line to the fan engine and a 2-inch pipe to each separate section of each heater. The radiation throughout the building is arranged for low pressure with separate supply and returns, and reducing valves are accordingly used in connection with the live steam supply. The water of condensation has thus to be pumped to the boilers, and a 6x4x6 inch Snider-Hughes Co. duplex steam pump and receiver has been installed for the purpose. The exhaust from both engine and pump is utilized as far as possible, being passed first through a Kieley oil eliminator and conveyed to the tempering coils and also to one section of each of the main heaters, these sections being in addition piped to receive live steam when necessary. In this connection the usual outboard exhaust pipe with back-pressure valve is furnished. Direct radiation has been provided for the corridors as well as for the vestibules.

The contractors for the heating and ventilating apparatus, which cost $8,500.00, were Messrs. Barr & Creelman, of Rochester.

The Simplon Tunnel excavation was carried on during July at the rate of 16.8 feet per day in the north heading and 23.4 feet at the south, according to "Engineering," which gives the total advance at the end of the month as 24,-849 feet at the north and 16,420 feet at the south. The rock temperature in the north heading is 127 degrees Fahrenheit. The flow of water in the north tunnel is 1.88 gallons per second, but in the south tunnel it is 243.1 gallons, and has caused much trouble.

The Durability of Steel in Concrete.

It has generally been assumed that steel embedded in concrete does not suffer any injurious changes, although an occasional instance is mentioned to show that the metal will be corroded under some circumstances. In order to obtain definite information on the subject, M. Breuillié undertook at La Chainette a series of experiments which are described by him in a recent issue of the "Annales des Ponts et Chaussées."

Four slabs of concrete-steel were first made in which the proportions of the Portland cement concrete were as follows:

No.	1	2	3	4
Cement, lbs.	1,323	1,323	1,764	2,204
Sand, cu. ft.	12.6	12.6	12.6	12.6
Gravel, cu. ft.	31.8	31.8	31.8	31.8

All slabs had an area of 36x39 inches and a thickness of 11.8 inches. The steel rods embedded in them were 3/16 inch in diameter and were arranged in the following order: About ¾ inch from the upper face there was placed a rectangular network of rods parallel to the sides and about 1½ inches apart, the outside rods being ¾ inch from the edge. One and one-half inches below the first a second layer was laid; a third 1½ inches below the second; a fourth 4 inches below the third; a fifth 1½ inches below the fourth; a sixth the same as the fifth. On the first layer of bars a netting of 3/32-inch wire was laid, and the mortar was pressed on it so as to form a tight coating. Six manometer tubes penetrated in each layer.

The first slab was subjected to a pressure of 12 meters (39.4 feet) of water in the morning of one day, which was taken off in the evening. For six days this operation was continued. The manometer tubes show that the water had penetrated into the block, impregnating it completely, and had reached the embedded steel. After these few days the plate was left in the open air exposed to the action of the weather. From time to time pieces of the concrete were taken from the block, and the metal was always found in perfect condition.

Two facts are to be noted: The surface of the metal was bright before it came into contact with the cement and dull after the metal was exposed by removing the cement. The mortar adhered to the steel at the edges in the parts protected by bitumen, but it did not adhere in the parts where the water had circulated. By additional experiments the author verified the above fact, that if steel bars, having a bright surface, were immersed in cement mortar during several days, the surface became dull after removal of the adhering mortar. It appeared that the mortar had attacked the surface of the steel. This action of mortar on steel explains the reduction of rust on steel bars in cement. The latter is a fact frequently stated and which can easily be verified by letting some bars take a slight layer of rust and then embedding them in cement mortar. The first bars which were removed from the mortar after three to five days showed still some rust stains. The last bars which were removed after 15 to 20 days were perfectly free from rust, which appeared to have given up its oxygen to the cement.

The water which passed through the concrete slabs was sampled before and after passing, and an analysis of the salts contained in it was made by the laboratory of the Ecole des Ponts et Chaussées. These salts came from the water as well as from the concrete block. Specimens collected after the pressure was stopped gave the results next tabulated. The table shows that water just before passing into the blocks after removal of pressure contains more mortar salts than the water which passed through the slab.

When sampied	Before passing.	After passing.
No. samples	3	4
	Grams.	Grams.
Silica	2.46	1.42
Aluminum and iron	3.60	2.32
Lime	17.70	15.60
Magnesia	Traces	Traces
Sulphuric acid	1.22	0.90
Chlorine	1.22	0.90
Loss on ignition	28.46	25.85

The three remaining slabs were subjected to the action of water under a pressure of about 50 feet. In spite of the rich proportion of cement, the use of a metal netting and the smoothening of the mortar, all three specimens, though more tight at the beginning than the best granite, were penetrated by the water after having been subjected to intermittent pressures. The water which passed through the plates as well as the water which came back from the upstream end was analyzed. The following table gives the results obtained:

Samples taken	Up-stream.	Down-stream.
No. samples	5	8
	Grams.	Grams.
Silica	3.20	1.52
Aluminum and iron	6.12	2.40
Lime	20.50	17.50
Magnesia	0.50	Traces
Sulphuric acid	1.59	1.13
Loss on ignition	26.98	28.27

The silica, aluminum and iron, magnesia and sulphuric acid come from the slabs only.

Comparing these proportions with those shown by an analysis of the cement, it was found that the proportion of iron and aluminum collected is much higher than that generally found in cement, 19 and 13 per cent. instead of 10.5.

When slabs 2, 3 and 4 were broken, the bars, which were bright when embedded, had become dull, and the metal did not adhere to the cement at the portions through which the water passed. Just as in slab 1, it appeared that the bars did not rust when they were surrounded by mortar, even when the water passed through the mortar.

The preceding seems to indicate that, first, a salt is formed by the action of cement on iron, and, secondly, this salt is dissolved by the water which penetrates into the concrete-steel.

If the cement attacks the steel and a chemical combination is formed, the weight of the steel must be more or less than before, according as the newly-formed body adheres to the steel or not. To verify this conclusion ten 2x2-inch plates were taken. Each little plate thus had 8 square inches surface. These were weighed and then embedded in Portland cement mortar; after 24 days they were taken out, carefully cleaned of all mortar, weighed and again put in the mortar. The same process was repeated after 14 days, and, finally, after 76 days, an increase in weight was noticed in every case, the amounts of milligrams being as follows:

Plate.	After 24 days.	After 14 days.	After 76 days.	Total.
1	4 mg.	2 mg.	4 mg.	10 mg.
2	1	5	5	11
3	6	4	5	15
4	4	3	7	14
5	3	3	5	11
6	4	3	6	13
7	6	3	5	14
8	5	2	5	12
9	4	4	5	13
10	6	2	4	12
Avge.	4.3 mg.	3.1 mg.	5.1 mg.	12.5 mg.

The increase in weight was very definite, and it increased with the length of time the metal was left in the mortar. An analysis of these plates, made at the laboratory of the Ecole des Ponts et Chaussées, only gave general indications that the increase in weight appears to be due to the formation of a silicate of iron.

To find the rate of increase in weight, fifty 2x2-inch steel plates were numbered from 1 to 50, weighed and embedded in cement mortar. Every five days a series of five plates was taken out and carefully cleaned by a thorough rubbing. The results obtained are tabulated below:

Increase after	Minimum.	Average.	Maximum.
5th day	—1	—3/5	0
10th "	0	1	2
15th "	3	4.2	6
20th "	3	4.6	7
25th "	5	5.8	7
30th "	5	6.4	7
35th "	5	6.0	7
40th "	5	6.6	8
45th "	7	7.4	9
50th "	8	9.4	11

The increase in weight, as can be seen, was quite regular, except between the thirtieth and fortieth day, during which period cold weather prevailed.

If a soluble salt had formed, the plates taken out from the mortar should lose weight under the action of water. Nos. 46 to 50 were twice put in constantly renewed water, and they lost part of their weight. After six hours the loss of weight was on an average 2 milligrammes, after a second immersion of seven hours the loss was 2.2 milligrammes. The tabulated results are as follows:

Plate.	Increase in weight.	Decrease after 1st immersion.	Decrease after 2d immersion.	Total.
46	8 mg.	3 mg.	1 mg.	4 mg.
47	11	2	3	5
48	8	1	2	3
49	10	2	3	5
50	10	2	2	4
Avge.	9.4 mg.	2 mg.	2.2 mg.	4.2 mg.

The salt which is formed at the contact surface of steel to cement seems to have a determining effect on the adhesion of the two bodies, and, as this salt forms slowly, the author decided to find out whether the adhesion takes place on the setting of the cement or whether it increases with age, the same as the salts do. Thirty plates, 1⅝x2¾ inches, were placed on a horizontal surface of a concrete block made in the proportion of 31.2 pounds of cement to 1 cubic foot of sand. The whole was left in a room, and the mortar hardened under ordinary conditions. The plates were torn off vertically in series, the first series after two days, the rest after every five days. The tests were such that only the adhesive resistance was shown and no friction between the two materials could take place. The average results of each series were as follows:

Contact period.	Average adhesion.
2 days	4 lbs. per sq. in.
7 "	9.5 " "
12 "	13.5 " "
17 "	16.2 " "
23 "	18.5 " "
27 "	18.8 " "

It may be stated that the adhesion increased uniformly and reached after 30 days a greatest value of 22 pounds per square inch, or about half of the adhesion which is generally assumed.

The results obtained do not give at the end of each period the least amount of adhesion which can positively be expected, and it is evident that it is not advisable to use higher values, though higher results can be obtained under special conditions. The author attempted to find the effect on the adhesion of leaving the plates in open air or keeping them in a hot room, but in no case were the results noticeably below the above, and in some instances they were much higher. In a special case, by mixing the cement after warming it in the sun, an adhesion of 34 pounds per square inch was obtained in five days, but it should be added that the plates did not then show any regularity in their adhesion to the mortar. The experiments convince the author that, (a) the cement attacked the iron, (b) water dissolved the composition which formed at the contact of the two materials, (c) the adhesion of the steel to the cement disappeared when water passed through the concrete-steel for a certain time, (d) the weight of the iron salts which adhere to the steel and the normal adhesion between the steel and concrete increased with the time.

Trade Publications.

The Westinghouse Electric & Mfg. Co., Pittsburg, has issued a revised edition of its circular concerning lightning protection. It explains injuries to electrical apparatus by lightning, outlines the functions of different classes of protective devices against such injuries and describes in detail, with many illustrations, the construction and installation of arresters, choke coils and static interrupters.

The Roebling Construction Co., 121 Liberty street, New York, has prepared a 102-page album of views of business buildings, industrial plants, residences and churches which have been supplied with its system of fire-proof floors and partitions. These buildings include many of the most notable architectural works of the last two years.

In The Engineering Record of August 2, there was printed a report by Dean & Main on several trials of a 300-horse-power De Laval turbine, operating under different conditions. This report has just been issued in pamphlet form by the De Laval Steam Turbine Co., 74 Cortlandt street, New York.

The inventor of the continuous sewage filter described in The Engineering Record of August 23, Mr. F. Wallis Stoddart, of Bristol, England, has issued a well-illustrated 40-page pamphlet describing its principles, construction and capabilities.

Mr. W. L. Dickinson, of Springfield, Mass., president of the Connecticut Valley Highway Association, has made an investigation of the results of the use of Warren's bituminous macadam pavement, and the report, which can be obtained from him, has been published with letters from city officials familiar with the work.

A 224-page book is needed to describe the twist drills, reamers, taps, dies, mills and cutters made by the Standard Tool Co., Cleveland, and to furnish the many valuable tables the company has prepared. These give the decimal equivalents for millimeter and drill gauges and fractions, full particulars of screw threads used in this country and abroad, standard pipe dimensions, and wire and screw gauges.

The Harrison Safety Boiler Works, Philadelphia, have issued two pamphlets concerning feed-water heaters, one referring to the advantages of the Cochrane open heater for collieries and other places where the boiler feed is liable to be poor, and one explaining the Sorge-Cochrane open heater and purifier for treating hard water chemically as well as by heat. In the latter the amount of chemical required can be determined from time to time by a simple color test and the supply regulated by a valve.

McIntosh, Seymour & Company, Auburn, N. Y., have issued a book containing a full description of the design of the various varieties of engines they build, ranging from the 20-horse-power high-speed type to the large vertical and horizontal units of several thousand horse-power employed in mills and power stations. Many elaborate tables of capacities and dimensions are furnished and the illustrations give views in numerous engine rooms of interest to steam plant designers.

The new edition of the heating catalogue of the J. L. Mott Iron Works, New York, is a well-illustrated book of 96 pages. It describes many types of hot-water heaters with capacities of 100 to 10,000 feet of radiation, steam boilers with a range of 300 to 8,000 feet, and radiators of many styles and forms.

The Magee Furnace Co., Boston, Mass., has issued a second edition of its "manual," a leather-bound book of 72 pages. The construction and dimensions of the steam and water heaters of various types made by the company are fully explained, but the greater part of the book is a collection of tables, standard drawings and suggestions valuable to the architect and fitter.

The new bulletins of the Bullock Electric Mfg. Co., Cincinnati, include the following: No. 1,002, direct-current multipolar "N"-type motors of ½ to 60 horse-power; No. 1,003, marine lighting and power sets; No. 1,012, direct-current multipolar "H"-type motors of 4 to 200 horse-power; No. 1,013, direct-current multipolar "H" and "HI"-type belt-driven generators of 3 to 500 kilowatts. The special features of design and construction are explained and the tables of dimensions are unusually complete.

The Hyatt Roller Bearing Co., Harrison, N. J., has issued a well-illustrated bulletin on the use of its well-known bearings for heavy duty at slow speed. Trucks, hoists, conveyors, transfer tables, cranes, cars and other apparatus are operated much more easily when fitted with these bearings, according to numerous testimonials in the pamphlet, which contains tables to assist in selecting bearings for given loads and shafts.

A handsomely illustrated description of its various types of cable railways for handling coal and merchandise has been prepared by the C. W. Hunt Co., Allen street, West New Brighton, N. Y. It is particularly interesting for the numerous illustrations of installations for important power plants and coal storage yards.

Personal and Obituary Notes.

Mr. Rolla W. Roberts has been elected city engineer of Saginaw, Mich.

Mr. J. H. McRee, city engineer of Wilmington, N. C., died suddenly in that city on September 9.

Capt. Francis R. Shunk, Corps of Engineers, U. S. A., has been ordered to St. Augustine, Fla., to relieve Capt. Herbert Deakyne.

Thomas E. Chandler, of the Chandler & Taylor Co., steam engine builders, of Indianapolis, died September 10 at the age of 70 years. He had been confined to his bed but ten days.

Mr. Eduardo J. Chibas, M. Am. Soc. C. E., of Santiago de Cuba, has been retained by the authorities of Guantanamo to plan a system of sewerage and sewage disposal works and to report on the improvement of the streets of that city.

In Asphalt Paving in New York the contractors use in most cases a fine, well-graded sand. Mr. W. H. Broadhurst, chemist of the Highway Department, states that the use of such sand together with a large amount of fine mineral dust permits of the use of a large percentage of bitumen containing a larger percentage of flux than is possible with a coarse sand. The effect of such improvement in formula tends largely to increase the life of the pavement. It should be noted in this connection that on Broadway, and on many downtown streets subjected to heavy traffic, Portland cement has been used for the fine mineral dust in place of powdered carbonate of lime. As Portland cement contains a larger amount of impalpable powder than does powdered carbonate of lime, the use of same with a fine, well-graded sand, and proper amount and quality of asphaltic cement, produces a very dense pavement mixture with a minimum percentage of voids. The result has been for the reasons above noted an asphalt pavement of the highest grade. In fact, it may be said that the feasibility of laying asphalt pavements on streets which sustain such heavy traffic as Broadway is due to these improvements in the asphalt mixture.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xviii and xxvii.

WATER.

Philadelphia, Pa.—Local press reports state that the following bids were opened Sept. 12 by Director of Pub. Wks. for constructing the pumping station to be erected at Delaware Ave. and Race St. in connection with the new high-pressure fire service: *a*, amount; *b*, time in days; *c*, price per cu. yd. for removal of old buildings; *d*, price per pile for pile driving: Geo. C. Dietrich, *a* $74,400, *b* 140, *c* $9, *d* $6.90; Ryan & Kelly, *a* $81,000, *b* 140, *c* $12, *d* $12; Henderson & Co., *a* $56,533, *b* 180, *c* $10.75, *d* $9.80.

The following bids are stated to have been opened Sept. 17 for a pumping station at Lardners Point (bids were on same specifications on which bids were made Aug. 12); the figures following the bids are, 1st, the number of working days to complete the foundations and superstructure for the engines; 2d, the number of working days to complete the entire work: Geo. C. Dietrich, $532,000, 145, 240; Millard & McGraw, $533,000, 150, 250; Henderson & Co., $637,000, 7 and 5 mos.; D. J. McNichol, $722,000, 310 days.

Sodus, N. Y.—Local press reports state that this town proposes to let a franchise for the construction of water works. Lewis H. Clark is said to be interested.

Cincinnatus, N. Y.—Engr. F. W. Moxley estimates the probable cost of a system of water works at $11,000, not including reservoir site, cost of springs and right of way.

New York, N. Y.—Bids were opened Sept. 18 by Robt. G. Monroe, Comr. of Water Supply, Gas & Electricity, for building an engine, coal and boiler house for high service works at Jerome Park Reservoir, Jerome Ave. between Van Cortlandt Ave. and Mosholu Parkway, as follows: Luke A. Burke, $123,000; Kelley & Kelly, $113,900; N. W. Ryan, $97,750; Chas. Scheidecker, $132,379; John R. Sheehan & Co., Inc., $111,700.

Homestead, Pa.—The Boro. Council has awarded the contract for the new addition to the water plant to J. Monroe & Son, of Pittsburg, for $4,500.

Newport, N. Y.—The proposition to issue $15,000 water works bonds is reported to have carried.

Paterson, N. J.—The following bids were opened Sept. 10 by the Jersey City Water Supply Co., for constructing the Parsippany Dike: A, Metropolitan Constn. Co., Jersey City; B, Hillpot & McCabe, Jersey City; C, Beckwith & Quackenbush, Mohawk, N. Y.; D, Higginson & Shannon, Jersey City.

Items and Quantities.	A	B	C	D
Clearing 8 acres	$50.00	$123.50	$50.00	$60.00

Totals	$119,480	$119,742	$123,073	$149,047

*Does not include cement.

South Deerfield, Mass.—Bids will be received by the Water Comrs. until Sept. 24 for constructing masonry dam and cleaning reservoir site on Roaring Brook near this village. J. B. Bridges, Chmn.

Ithaca, N. Y.—The Ithaca Light & Water Co. has awarded the contract for the construction of the dam on its property in Six Mile Creek to Tucker & Vinton, of New York City, for $34,225.

Nassau, N. Y.—Bids will be received by the Village Bd. of Trus. until Oct. 1 for furnishing material and constructing a system of water works. Bids will be received separately for building reservoir, dam, laying pipe, with hydrants, valves, special castings, etc. Henry N. Smith, Pres.; E. W. Moxley, Engr.

Aiken, S. C.—F. W. Wessels, Chmn. Water Wks. Com., writes that the contract for drilling an artesian well 10-in. in diameter, minimum depth 55 ft., maximum depth 1,000 ft., was awarded Sept. 12 to Perry Andrews & Bro., of Atlanta, Ga.

Richmond, Va.—A correspondent writes that the City Council has received a proposition from a company (of which John C. Robertson, Times Bldg., Richmond, is said to be able to give information) to furnish the city with water from a clean stream.

Baltimore, Md.—The Water Com. has reported favorably on the resolution to appoint a commission to consider the feasibility of establishing a filtration plant.

Portsmouth, Va.—Press reports state that Gen. Mgr. of the Portsmouth, Berkley & Suffolk Water Co., has been directed to proceed at once with contemplated improvements. Judge L. R. Watts, Pres.

Salem, Va.—Paul S. Nugart, professor of civil engineering in Syracuse University, Syracuse, N. Y., is said to have been appointed by the town to make improvements in the water supply.

Richmond, Va.—Mayor Taylor has approved a resolution instructing the Committees on Finance and Water to report a scheme for raising $350,000, to be used for clear water.

Atlanta, Ga.—Mayor Mims in a communication to the Council urges the issue of $400,000 for the purpose of perfecting the water works system.

New York, N. Y.—Norton & Dalton have been awarded a contract for laying water mains in a number of streets, bids opened Sept. 4, as follows. The work includes the setting of 3 20-in. stop cocks, 42 12-in. stop cocks, 59 6-in. stop cocks, and 121 hydrants.

Curb, 1,100 lin. ft.	.10	.20	.10	.01	.10	.05
Totals	$93,243	$112,140	$107,389	$104,635	$98,510	$96,950

Bidders all of New York City except Henry Lipps., Jr., his address being Ellicott Ave., Williamsbridge.

Westbrook, Minn.—Bids will be received by the Village Council until Sept. 29 for $7,000 bonds, the proceeds to be used to construct a system of water works, for both public and private use. John E. Villa, Village Recorder.

Kewanee, Ill.—Bids will be received by the Bd. of Local Improv. until Sept. 24 for laying 4,050 ft. of 6-in. (33 lbs. per ft.) and 72 ft. of 4-in. (22 lbs. per ft.) cast-iron pipe, 5 Ludlow fire hydrants, five 6-in. gate valves and boxes, and 2,500 lbs. of special castings. F. F. Whiffen, Pres.

Galion, O.—City Clk. J. O. Ross writes that on Sept. 15 it was voted to issue $50,000 bonds for the construction of water works.

Eureka, Ill.—This city is said to be considering the erection of a water tower and tank at a cost of $4,000.

Kiester, Minn.—Press reports state that this town voted for water works, and work is to be started without delay.

Roanoke, Ill.—The matter of establishing water works for fire protection is said to be under consideration.

Rantoul, Ill.—The Village Bd. is inspecting various water works' systems. A 75,000-gal. tank is favored and 6-in. mains.

Chicago, Ill.—Bids are wanted Sept. 24 for furnishing material and constructing the intake, foundation and pump wells for the 39th St. Pumping Station, etc. F. W. Blocki, Comr. of Pub. Wks.

Albia, Ia.—W. A. Seevers, of Oskaloosa, Ia., is said to have made a proposition to furnish $100,000 if a similar sum is raised here, to install a complete electric light and water system with an interurban line to Hilton and other points.

Webster Grove, O.—Bids will be received at the office of the City Clk. of Webster Grove, until Oct. 6 for furnishing approximately the following quantities of cast-iron pipe and special castings; all net tons: 105 tons of 12-in., weighing 80 lbs. per ft.; 75 tons of 10-in., 60 lbs. per ft.; 150 tons of 8-in., 45 lbs. per ft.; 260 tons of 6-in., 33 lbs. per ft.; 350 tons of 4-in., 21 lbs. per ft.; 12½ tons of special castings. Edw. S. Hart, Chmn. Com. on Water Supply, Clayton, Mo.; Wm. H. Bryan, Consulting Engr., Lincoln Trust Bldg., St. Louis, Mo.

Cass Lake, Minn.—The Cass Water, Light & Power Co. will in about 2 weeks award the contract for laying about 4,000 ft. of 8 and 6-in. water mains. For all information address the above company.

New Bremen, O.—It is stated that bids are wanted Sept. 23 for water works to cost about $30,000. G. A. Kunning, Clk.

Mt. Clemens, Mich.—The Bd. of Pub. Wks. recommends that a new engine and a 3,000,000-gal. pump be purchased for the water works.

Grinnell, Ia.—The Grinnell Water Co. has contracted with Colcon & Daily, of Mt. Pleasant, for the construction of a dam for $5,000.

Hamilton, O.—At a recent citizens' meeting the special committee appointed on July 9 to investigate the needs of Hamilton's water works system recommended a new pumping station to cost $83,600.

Youngstown, O.—The Bd. of Water Wks. Trus. has bought 8 acres of land as a site for a filtration plant. Plans and estimates for a plant to filter Mahoning River water will be made at once, according to local press reports.

Minneapolis, Minn.—The sum of $200,000 has been set aside by the Water Works Com. for the construction of 2 large distributing mains for the city water system, and about $25,000 will be expended for smaller mains.

Zeeland, Mich.—The Village Bd. has let to Arbuckle-Ryan Co., of Toledo, O., a contract to install a complete water and lighting system within 60 days.

Westerville, O.—Bids will be received by the Water Wks. Trus. until Sept. 26 for furnishing material and erecting the following items for water works: a frame building for pumping station with slate roof, a brick receiving reservoir, 2 steel pressure tanks, with valves and connections erected. All bids are to be made separately for labor and material. J. P. Force, Consulting Engr.

Abingdon, Ill.—Bids are wanted Sept. 23 for erecting a power house for water works station, 1 deep well pump, and necessary attachments, for water tower and foundations. Geo. Cadogan Morgan, Engr., 808 Royal Insurance Bldg., Chicago.

Dallas, Tex.—The City Council has adopted the report of the Water Comrs. and Com. on Pub. Improvements, recommending that Chester B. Davis, of New York City, be employed to make surveys, with plans and specifications and estimates of cost for a pipe line to Bachman reservoir.

Minden, La.—It is proposed to construct water works. W. H. Webb, Engr. in Charge.

Perry, Okla. Ter.—The Council is said to be considing the matter of sinking an artesian well.

Huntsville, Tenn.—Press reports state that this city is about to purchase several tons of water pipe for extensions in E. and W. Huntsville.

Miami, Ind. Ter.—Press reports state that the Miami Artesian Water & Electric Light Co., which has a capital of $50,000, proposes to put in a plant. Jas. K. Moore, Secy.

Jackson, Miss.—A special committee has been appointed to secure a pure water supply from artesian wells; $40,000 has been appropriated.

Tuscumbia, Ala.—Col. D. A. Tompkins has a franchise for water works and electric lights for this city, and it is stated that the plant, which will be located at Sheffield, will cost $150,000, Tuscumbia to receive a supply of water and lights from that city, Tennessee River water being utilized. The extension to Tuscumbia is estimated to cost $50,000, with an additional $25,000 to be expended in filtering the water. C. H. Campbell, of Charlotte, N. C., is said to represent Col. D. A. Tompkins.

Dyersburg, Tenn.—It is stated that bids are wanted Sept. 29 for constructing water works and an electric light plant, to cost about $40,000. W. A. Fowlkes, Jr., Mayor.

Tonopah, Nev.—J. H. Ralston, of Carson City, Nev., writes that the probable cost of the 60 miles of wood water-pipe line which it is proposed to construct to Tonopah will be $1,000,000.

Walla Walla, Wash.—Press reports state that steps are being taken to develop and extend the water system; the plan provides for several miles of new pipe.

Tacoma, Wash.—The matter of extending the water mains to outlying districts is under consideration.

Mt. Vernon, Wash.—Press reports state that the Skagit Improvement Co. has been incorporated, with a capital stock of $100,000, and will put in a water works system for Sedro-Woolley and Mt. Vernon. The incorporators are W. R. Morgan, W. E. Guerin and H. F. Guerin.

Tacoma, Wash.—City Comptroller Lister estimates the total cost of operating the city department for the coming year at $719,408; of this amount $75,000 is for a new water supply plant to be built at South Tacoma, and $25,000 for a new service to furnish increased pressure in the more elevated portions of the city.

The Council has passed a resolution for the extension of water mains on certain streets in the Sixth and South Side additions.

Del Norte, Colo.—The Continental Land & Irrigation Co. has been incorporated, with a capital of $200,000, to operate in Rio Grande, Costilla, Saguache, Conejos, Archuleta, Mineral and Hinsdale counties. Principal office in Del Norte. Directors: Theo. J. Lakenan, Wm. H. Cochran, Wilber E. Shaw and A. J. Weiss.

Marysville, Cal.—The State Bd. of Examiners has approved plans and specifications for the first of the proposed Yuba River barriers, which is to cost $35,000. Total appropriation, $800,000.

Salt Lake City, Utah.—City Engr. Kelsey has filed a notice to the effect that the city has located and appropriated a tract of land in Parley's Canyon for a reservoir and dam site.

Nampa, Idaho.—Local press reports state that plans and estimates are being prepared for water works.

Lincoln, Neb.—The City Council has ordered the City Water Comr. to lay 28 blocks of water mains, 4, 6 and 8-in. pipe to be used.

Lidgerwood, N. D.—Bids are wanted Sept. 29 for constructing a water works distribution system, according to plans prepared by Prof. J. J. Flather, of Minneapolis. John Nuding, City Aud.

Winnipeg, Man.—The time for receiving bids for cocks, pipe, hydrants, meters, etc., is Sept. 29, as advertised in The Engineering Record.

Armstrong, B. C.—It is stated that bids are wanted Sept. 30 for water works to include 3 miles of mains. Jos. McDonald, Recorder.

SEWERAGE AND SEWAGE DISPOSAL.

Scranton, Pa.—Jos. P. Phillips, Ch. Engr., Dept. of Pub. Wks., writes that bids will be received until Sept. 29 for constructing the 19th Dist. Sewer. The work will contain about 60,000 ft. of various sized pipe and brick sewer, and is estimated to cost about $180,000.

Boston, Mass.—Bids are wanted Sept. 24 for sewerage works in Rosemont St.; also until Sept. 25 for sewerage works in Blandford and Cummington Sts. Jas. Donovan, Supt. of Streets.

Bayonne, N. J.—The Council has instructed the City Engr. to prepare plans and specifications for sewers in E. 16th, W. 17th and W. 43d Sts.

New Brunswick, N. J.—Bids are wanted Sept. 25 for laying a vitrified pipe sewer in Ray St. Wm. F. Harkins, Street Comr.

Amherst, Mass.—The Selectmen are considering the question of sewage disposal.

Westfield, Mass.—Town Engr. Oren E. Parks writes that the following bids were opened Sept. 13 in response to a readvertisement for the completion of Section 1 of the storm water sewer system: A, Seymour & Newell, Springfield, $34,765 (awarded); B, Robert D. Maynard, Springfield, $35,344; C, Long & Little, Leominster, $37,077; D, D. W. Mellen, Springfield, $37,566; E, G. M. Atkins & Co., Palmer, $38,536; F, Bruno, Salomone & Petitti, E. Boston, $41,568. For detail bids see accompanying table:

Items and Quantities.	A	B	C	D	E	F
Earth excav.:						
54-in. sewer, 4,610 ft.	$1.25	$1.50	$1.50	$1.65	$2.00	$2.05
36-in. sewer, 98 ft.	1.25	1.00	1.00	1.65	1.50	2.00
Siphon	$100	$100	$140	$195	$150	$125
8-in. sewer, 670 ft.	.30	.25	.40	.50	.35	.40
Br. mas., 1,890 cu. yds	12.00	12.15	13.00	12.25	12.00	13.35
Con. mas., 695 cu. yds.	7.25	6.00	5.75	7.00	7.00	7.50
Lumber, 15 M. ft.	20.00	30.00	30.00	30.00	40.00	35.00
Rock excav., 160 cu. yds.	3.50	3.00	4.00	5.00	4.00	3.50

Mortar for brickwork, Portland cement, 1:2½; concrete masonry, Portland cement, 1:3:6; earth excavation, average cut 9.7 ft.

Schenectady, N. Y.—The Common Council has authorized the construction of a number of new sewer mains.

Harrisburg, Pa.—A. C. Stamm, Secy. Bd. of Pub. Wks., writes that the detail bid of S. M. Neff, 120 Liberty St., New York City (successful bidder), for the construction of the intercepting sewer, was as follows (bids opened Sept. 3): Parabolic concrete and expanded metal sewers complete, 5-ft. at $9.80 per lin. ft., 4-ft. at $8.95; 5-ft. rectangular concrete sewer with steel beams and concrete top, concrete walls and bottom, complete at $15 per lin. ft.; outfall sewer complete, including the manhole at bank of Susquehanna River, the 36-in. vit. sewer pipe, the 36-in. c. i. pipe excavation of river bottom, etc., $6,000 lump sum; silt basin and regulating chamber at Schuylkill St., including regulating valve, float, float chamber, manholes, screen bars, inlet pipes, etc., complete, $800 lump sum; for each manhole complete on intercepting sewer, $65; for each silt basin on inverted siphon and on connections with intercepting sewer where no inverted siphon is used, complete, $250; for each manhole containing a flap gate, to be built on existing sewers, complete, $225; for each manhole at discharging ends of inverted siphons, complete, $60; cast iron pipe, 5-in. and 8-in., with leaded joints, in inverted siphons, at $3 and $4 respectively, per lin. ft.; 10-in. and 12-in. in connections with intercepting sewer at $6 and $7 respectively, per lin. ft.; yellow pine timber in foundations, including excavations for placing same, etc., $45 per M. ft. B. M.; spruce timber in foundations, $45 per M. ft. B. M.; sheeting, shoring, bracing and sheet piling, $35 per M. ft. B. M.; vitrified sewer pipe, with cemented joints, 8-in., 10-in. and 12-in., at $2.50, $2.75 and $3 respectively, per lin. ft.; extra concrete, mixed 1 part cement, 3 parts sand and 6 parts broken stone, $7.50 per cu. yd.; extra gravel or broken stone filling, $1.75 per cu. yd. The total amount of contract is about $167,227.

McKeesport, Pa.—The Common Council has passed ordinances as follows: for sewers in Pope Alley, Butler St., "A" Alley and Douglass St., for a sewer in Packer St., a sewer in Sinclair and Jerome Sts. and for a $75,000 bond issue for Crooked Run sewer.

Erie, Pa.—The City Engr. has reported the cost of the city's portion of a sewer from the lake to the intersection of East and McCarter Ave., as $18,823; also of East Ave. sewer, McCarter Ave. to 26th St., as $20,087.

Geneva, N. Y.—Bids will be received until Sept. 24 by Chas. S. Boyd, State Supt. of Pub. Wks., Albany, for constructing sewers to conduct the waters of Washington and Cemetery Creeks from a point beyound the terminal of said creeks, through the towing path extended, of the Cayuga and Seneca Canal, in said city; also for repairing and protecting the extended towing-path of the Cayuga and Seneca Canal across the harbor at Geneva.

Solvay, N. Y.—Village Clk. A. E. Waterfield writes on Sept. 15 the Bd. of Trustees was authorized to obtain a temporary loan of $8,400 to pay for building a sewer in the Draper tract, and to complete the pumping and lighting plant, which is now being operated by steam.

East Washington, Pa.—Boro. Engr. McAdam has reported to the Boro. Council that 5,000 ft. of sewer will be necessary to complete the system, and he has been instructed to prepare plans for same.

North Braddock, Pa.—Press reports state that several thousand dollars are to be expended by this Boro. for sewering and paving the 1st Ward.

East Greensburg, Pa.—The Boro. Council has passed an ordinance authorizing the construction of a public sewer, and a branch sewer, 10, 8 and 6-in. pipe to be used. H. F. Seanor, Ch. Burgess.

Brooklyn, N. Y.—The following bids were opened Sept. 17 by J. Edw. Swanstrom, Boro. Pres., for constructing sewers in 60th St. from 14th Ave. to 19th Ave., etc., only the largest items being given: A, John J. Creem; B, James Malloy & Co.; C, Jas. H. Holmes & Co.; D, John McNamee:

	A	B	C	D
Brick sewer:				
162-in., 15 ft.	$65.50	$55.00	$31.00	$65.00
156-in., 4,015 ft.	61.50	55.00	31.75	53.00
144-in., 660 ft.	43.00	49.00	27.00	45.00
78-in., 60 ft.	20.00	21.00	15.00	20.00
30-in., 100 ft.	5.00	4.00	5.00	4.50
Vit. pipe:				
24-in., 100 ft.	5.00	3.50	3.75	4.00
18-in., 100 ft.	4.00	3.00	3.00	3.00
6 manholes "A"	400.00	900.00	150.00	500.00
7 manholes "B"	50.00	60.00	125.00	75.00
8 manholes "C"	35.00	65.00	75.00	35.00
Receiving basins, 16	100.00	100.00	87.00	95.00
Planking, 680 M. ft.	20.00	20.00	17.00	20.00
Sheeting, 2,300 M. ft.	.01	20.00	17.00	20.00

Lancaster, N. Y.—Surveys are being conducted for the purpose of establishing a road and sidewalk grade line and also preparatory to the building of a sewer and drainage system.

Atlanta, Ga.—Mayor Mims in a recent communication to the Council, recommends the issue of $400,000 bonds for the improvement of the sewer system by extending the various trunk sewers to the city limits.

Council Bluffs, Ia.—The Council has adopted resolutions for an 8-in. sewer in E. Pierce St., and for the construction of a sewer in Williams St.

Edgerton, Wis.—Edw. Ruger, of Janesville, Wis., is said to be making a survey for a sewerage system.

Columbus, O.—Local press reports state that City Engr. Julian Griggs has now completed plans for the West and South Side sewer sections of the main trunk system, and also of the central relief section covered by the $265,000 bond issue recently accepted by the sinking fund trustees.

Wapakoneta, O.—It is stated that bids are wanted Sept. 29 for constructing sewers in certain streets. C. E. Fisher, City Clk.

Cincinnati, O.—The Bd. of Pub. Service has decided to construct a sewer in Observatory road from Edwards road to Crawfish creek trunk sewer.

Venice, Ill.—Press reports state that the City Council has under consideration the question of issuing $50,000 bonds for the construction of a sewerage system.

Clay Center, Kan.—Citizens are considering the construction of a municipal system of sewers.

Indianapolis, Ind.—The Bd. of Pub. Wks. has adopted a resolution for a main sewer in the northeast part of the city, to be known as the Valley Ave. sewer; said sewer, which will be 1¾ miles in length, will begin with 12-in. pipe and will connect with 14th St. sewer at a diameter of 4½ ft., 3-ring brick. Total estimated cost, $30,000.

Newton, Ia.—The City Council has been petitioned for the construction of 2 sewers.

Fairfield, Wis.—J. B. Ashley, of Baraboo; Mr. Palmer, of Fairfield, and A. J. Turner, of Portage, have been appointed by Judge Siebecker as a Comn. to examine and report upon the practicability of draining the marsh bordering on Leach Creek, in Fairfield, Sauk Co., and a tract in Caledonia, Columbia Co.; the district embraces some 6,500 acres.

Kaukauna, Wis.—Local press reports state that this city is soon to build an addition to its sewer system in the 2d Ward, which is likely to cost $15,000.

Sebring, O.—The County Comrs., Youngstown, have decided to make a survey for a large drain or open sewer for this village.

Lansing, Mich.—City Engr. H. A. Collar writes that the construction of a sewer 12,255 ft. long is proposed; the size to vary from pipe 15-in. in diameter to oval form, of brick 48x62 ins.; said sewer will absorb a creek that flows through the northwestern part of the city. Probable cost, $51,500.

Marshalltown, Ia.—The City Council has ordered the construction of a sewer in the First Ward.

Green Bay, Wis.—Sewer bonds to the amount of $50,000 were recently sold by the City Council.

Portland, Mich.—Village Clk. D. F. Goss writes that pipe sewers are to be laid. W. F. Sellick, Chmn. of Street Com.

Ironton, O.—Bids are wanted Oct. 2 for constructing several sewers in Dist. No. 4. Geo. H. Davies, City Clk.

Glenville, O.—Bids will be received by B. F. Davies, Jr., Village Clk., until Oct. 4 for constructing main storm water sewers in portions of several streets.

Akron, O.—Bids are wanted Sept. 27 for constructing local sewers in several streets; also until Oct. 11 for constructing a main trunk sewer in and through districts Nos. 3 and 10, including catch basins, manholes, ventilators, etc. Chas. H. Isbell, Clk. Bd. City Comrs.

Jeffers, Minn.—Bids will be received by the Village Council until Sept. 25 for constructing a sewer in this village. M. N. Rivers, Village Recorder.

Massillon, O.—Bids will be received by the Sewer Comrs. until Sept. 27 for furnishing material and constructing sanitary sewers in Duncan and Walnut Sts. Orlando C. Volkmor, Clk.

Bucyrus, O.—Bids are wanted Sept. 25 for constructing sewers in portions of East Warren and West Warren Sts. C. P. Bryant, City Engr.

Youngstown, O.—Columbiana and Mahoning Counties have under consideration plans for the construction of a drainage canal about 5 miles long. Estimated cost, $100,000. J. A. Brooks, of East Liverpool, is one of the Comrs. for Columbiana Co., and J. W. Van Auken, of Youngstown, is one of the Comrs. for Mahoning Co.

St. Louis, Mo.—The following bids were opened Sept. 16 by the Bd. of Pub. Improv., R. P. Garrett, Engr., for constructing joint district sewers in Rock Spring Joint Sewer Dist.:

Items and Quantities.	Hill-O'Meara Con. Co.	Heman Con. Co.
Earth excav., 40,000 cu. yds.	$.68	$.65
Loose rock excav., 600 cu. yds.	2.50	3.00
Solid rock excav., 200 cu. yds.	4.00	4.00
Quicksand excav., 10 cu. yds.	5.00	10.00
Extra earth furnished, 10 cu. yds.	.60	.50
Class "A" concrete, 10 cu. yds.	8.00	7.00
Class "B" concrete, 270 cu. yds.	7.00	6.00
Class "C" concrete, 600 cu. yds.	6.00	6.00
Rubble stone mas., 10 cu. yds.	6.00	6.00
Br. masonry, 6,800 cu. yds.	9.75	10.00
Vit. br. masonry, 530 cu. yds.	12.00	13.00
6-in. pipe sewers, 50 lin. ft.	.25	.20
9-in. pipe sewers, 10 lin. ft.	.40	.30
12-in. pipe sewers, 10 lin. ft.	.45	.40
15-in. pipe sewers, 10 lin. ft.	.50	.50
18-in. pipe sewers, 10 lin. ft.	.75	.70
21-in. pipe sewers, 10 lin. ft.	.95	1.00
24-in. pipe sewers, 10 lin. ft.	1.50	1.00
Junction in br. sewers, 230 pieces	.80	1.00
Cast iron, 7,500 lbs.	.03½	.03
Wrought iron, 2,000 lbs.	.04½	.04
Lumber in trench, 100 M. ft. B. M.	27.00	30.00
Timber found., 1 M. ft. B. M.	37.00	40.00
Drain pipes, 1,000 lin. ft.	.30	.50
Totals	$111,477	$113,069

Burlington, Ia.—City Engr. E. Steece writes that the City Council has ordered South and West Hill sewer system, 10¼ miles, tile and brick; North Oak system, 2 miles; Central Ave. and Arch St. sewer, 2,000 ft.

Monmouth, Ill.—Bartlett & Kling, of Galesburg, Ill., on Sept. 13 were awarded the contract for sewage disposal plant, including septic tank (bids opened Aug. 30.).

Girard, O.—City Clk. E. L. Hauser writes that the Council is asking for plans and specifications for a sewerage system and disposal plant.

Decatur, Ind.—Bids are wanted Oct. 1 for constructing tile sewers in several streets. D. M. Hower, City Clk.

Nashville, Tenn.—A bill is before the City Council to appropriate $73,000 to extend the Edgefield branch sewer.

Honey Grove, Tex.—The question of establishing a $6,000 sewer system is said to be under consideration.

Toronto Junction, Ont.—The Town Council is said to be considering plans prepared by R. E. Speakman for sewage disposal.

Toronto, Ont.—The City Engr. is said to recommend the installation of a separate sewerage system for the East End Dist. Estimated cost, $40,000.

BRIDGES.

Harmony, Pa.—Press reports state that the Engineering Dept. of the B. & O. R. R. will shortly begin the building of 3 highway bridges in this city, on the Plattsburg Div. J. M. Graham, Ch. Engr., Baltimore, Md.

Springfield, Mass.—John A. Bennett, of Boston; Geo. H. Mellen, of Newton, and Geo. W. Bishop, of Athol, have been appointed as a R. R. Commission to act in the matter of alteration to bridges over the Boston & Maine tracks at Plainfield St. and the Berkshire St. bridge across Boston & Albany tracks.

West Hartford, Conn.—Town Clk. Henry C. Whitman writes that on Sept. 10 it was voted to construct a bridge across Trout Brook on Fern St.; cost of bridge and approaches, $4,090.

Reading, Pa.—The Viewers have reported to the Court recommending the building of a steel bridge across Schuylkill River at 6th St., to have a 20-ft. roadway, 5-ft. walks, with plank flooring, and consist of 2 spans, one 190 ft. long, the other 130 ft. long; estimated cost, $75,000.

Erie, Pa.—The City officials have received an offer from the Pittsburg & Eastern R. R. Co. to contribute $20,000 toward the construction of a bridge, provided the structure is placed at the Buffalo road crossing.

New Orleans, La.—Geo. G. Earl, Gen. Supt. Sewerage and Water Bd., writes that all bids opened Aug. 12 for sewers were rejected Sept. 3. A summary of the bids follows and the detailed bid of Contract B is given in the accompanying table:

	Estimated value.	Thos. F. Moore & Co., Syracuse, N. Y.	John Dowdle, New Orleans.	The U. S. Const. Co., Milwaukee, Wis.
Contract A	$490,710	$608,878.40	$700,428.50	....
Contract B	556,262	715,521.80	714,549.25	$813,325.05
Contract C	594,397	882,141.45	886,891.75	863,706.85

Items and Quantities.	John Dowdle, New Orleans.	Thos. F. Moore & Co., Syracuse, N. Y.	The U. S. Const. Co., Milwaukee, Wis.
Circular brick sewers:			
5-ft. 6-in., 17.3 to 20.3 ft. deep, 2,660 ft.	$27.50	$29.22	$30.50
5-ft. 3-in., 17.0 to 18.0 ft. deep, 250 ft.	24.60	26.90	27.65

Center Rutland, Vt.—The Selectmen have decided to call a town meeting Sept. 22 to decide the matter of contributing 40 per cent. of the cost (estimated at $4,500) of constructing a combination bridge for highway and track purposes in this city. The Rutland St. Ry. Co. has offered to pay the remaining 60 per cent. W. W. Wilkins, Chmn. Selectmen; David Fox, Mgr., Rutland St. Ry. Co., Rutland.

Albany, N. Y.—Deputy Supt. of Pub. Wks. Winslow M. Mead writes that the contract for constructing a bridge over Allegany River, on Allegany Indian Reservation, in the town of South Valley, has been awarded to Wm. H. Schmidt, of Buffalo, N. Y., for $25,311.

Harrison, N. J.—See "Railroads."

Boston, Mass.—The abutments of the Wellington bridge are about completed and it is stated that the Metropolitan Park Comrs. will be ready in a short time to receive bids for constructing the bridge and the draw.

Baltimore, Md.—Road Engr. W. W. Crosby recommends the building of a steel bridge across Georges Run, on Beckleysville Road, which will replace present wooden structure.

Hartford, Ind.—The Co. Comrs. of Blackford and Grant Cos. have agreed to build a joint county bridge across Walnut Creek, east of Hartford.

Washington, Ind.—The Co. Council has appropriated $3,500 to aid in the building of an iron bridge across White River, west of this city; $10,000 has been voted for this bridge, and $1,500 raised by subscription. The cost of the construction (contract for which is to be awarded in the near future) is not to exceed $15,000.

Three Rivers, Mich.—Jackson Bros., of this city, are reported to have secured the contract to construct a bridge across St. Joseph River for $14,900, the city to do all the filling. The bridge is to consist of 5 concrete arches, 3 40-ft. and 2 20-ft. long.

Hinckley, Minn.—A petition is in circulation to vote bonds for a bridge across Kettle River.

Huron, O.—It is stated that the officials of the Lake Shore Electric Ry. have submitted to the War Dept. at Washington, plans and specifications for a swing bridge to be built across Huron River, in this city, at a cost of $25,000. B. Mahler, Pres., Cleveland, O.

East Grand Forks, Minn.—Bids will be received by the City Council until Oct. 7 for constructing 2 approaches for the proposed bridge across Red Lake River, between Washington and Michigan Aves. Henry Harm, City Recorder.

Frankfort, Ind.—Bids will be received by the Bd. of Co. Comrs. until Oct. 6 for constructing several bridges, including a steel truss bridge, a stone brick arch, and a stone arch bridge. Address Co. Aud.

Watertown, Wis.—C. T. Loweth, Engr. & Supt. Bridges & Bldgs., Chicago, Milwaukee & St. Paul Ry., Chicago, Ill., writes that said company proposes to build at Watertown, across Rock River, an arch of cut stone backed with concrete; work to be done by the Ry. Co. A. G. Bennett, of Watertown, Engr. in Charge.

Halo, O.—It is stated that a petition is being circulated for the extension of the Boulevard from Halo to Akron city limits. Should this be done it would necessitate the building of a viaduct across the canal in this city.

St. Bernard, O.—The Bd. of Control has granted the Miami & Erie Canal Transportation Co. permission to raise and lengthen the bridges over the canal from St. Bernard to Butler Co. line.

Gas City, Ind.—Press reports state that the construction of a bridge is being considered. Probable cost, $12,000.

Kansas City, Mo.—The construction of an $85,000 viaduct at Guinotte and Lydia Aves. by the Missouri Pacific and Alton railroads, the Metropolitan St. Ry. Co. and the city, is being considered.

Marion, Ia.—The Co. Bd. of Superv. has been petitioned to construct a bridge across Cedar River, at what is known as Upper Palisades.

Peoria, Ill.—It is stated that the City authorities may employ an expert to estimate the cost of constructing a wagon bridge in this city.

Mason City, Ia.—The building of a stone bridge across Willow Creek at State St. is being considered.

Jonesboro, Ind.—The Co. Council has appropriated $14,000 for a bridge across Mississinewa River above Jonesboro, in Mill Township.

Huntington, Ind.—The Co. Comrs. have surveyed the Wabash River bridge on Warren Road, with a view to the building of a structure which will accommodate both wagon traffic and traction cars.

Canton, O.—Bids will be received by the Co. Comrs. until Oct. 11 for constructing a bridge at Linden Ave., having a 50-ft. span and 50 ft. wide.

Indianapolis, Ind.—It is stated that bids are wanted Oct. 8 for constructing a bridge across Eagle Creek. Harry B. Smith, Co. Aud.

Chillicothe, O.—The Co. Comrs. have decided to build a bridge across Haynes Ford, in Paint Creek, to have a 140-ft. span.

Stephenson, Mich.—The Co. Road Comrs. are reported to be considering the building of an iron bridge in this town.

Nevada, Ia.—Local press reports state that an agreement has been reached between the city and the officials of the Des Moines, Iowa Falls & Northern Ry. whereby a steel bridge is to be built where said railroad crosses the highway at Indian Creek.

Lawton, Okla. Ter.—Press reports state that the Secy. of the Interior, at Washington, D. C., has approved the building of 10 bridges in Comanche County.

Hillsboro, Tex.—See "Paving and Roadmaking."

Everett, Wash.—City Engr. Boyle recommends that a $50,000 steel bridge replace the condemned Everett Ave. structure. Maj. Mills, Corps Engrs., U. S. A., recommends that it be constructed 175 ft. further up stream.

Cottage Grove, Ore.—The Co. Comrs. have ordered the building of a wagon bridge at Cottage Grove.

Caldwell, Idaho.—City Clk. Edgar Meek writes that the contract for building a 352-ft. bridge across Fayette River has been awarded to Pueblo Bridge Co., Pueblo, Colo., for $39,980.

PAVING AND ROADMAKING.

Ebensburg, Pa.—Bonds to the amount of $11,000 for street improvements, are reported to have been voted at a recent election.

Freehold, N. J.—The Monmouth Co. Bd. of Chosen Freeholders has adopted a resolution authorizing the Com. on Freehold and Eatontown road to have a plan, maps and survey made, with estimates of cost for building a macadam road. Engr. Forman of said Bd. has placed the estimated cost of building the Manalapan and Freehold road of macadam (total length 6.30 miles) at $47,495; maps, etc., for this road have been referred to the State Road Comr. for his approval.

Morristown, N. J.—The County and Town Road Committees have decided to macadamize a portion of James St.; the county to pay for the 12 ft. strip in the center of the road.

Jersey Shore, Pa.—The proposition to issue $28,000 street improvement bonds is reported to have carried.

Brooklyn, N. Y.—Bids are wanted Oct. 1 for regulating and repaving with asphalt on portions of 3 streets, in all 12,971 sq. yds.; also for regulating, regrading and repaving with granite (12,690 sq. yds.) on a sand foundation the roadway of Varick Ave.; also for regulating, grading, curbing and laying cement sidewalks, in all about 48,120 sq. ft. of cement sidewalk. J. Edw. Swanstrom, Boro. Pres.

Ilion, N. Y.—City Engr. J. D. Ringwood writes that the contract for brick paving (bids opened Sept. 10) has been awarded to W. T. O'Connor, of Syracuse, at $2.30 per sq. yd. for Mack brick; total, $7,246.

West Hartford, Conn.—Town Clk. Henry C. Whitman writes that it was voted on Sept. 10 to provide for macadamizing a portion of Fairview St.

Troy, N. Y.—City Engr. E. R. Cary writes that on Sept. 9 the contract for improving 2d Ave. was awarded to P. H. Dumary & Co., Albany, N. Y., at the following prices: 34,750 sq. yds. of brick pavement on 6-in. concrete, at $2.17, $75,207; 24,500 sq. yds. of brick pavement on 8-in. concrete, at $2.23, $54,635; 26,250 ft. of curb, at 87½ cts.; 1,000 ft. old curb reset, at 35 cts.; 1,250 ft. old bridging relaid, at 45 cts.; 32 catch basins, at $95; 30 truck basins, at $14.50; 22 old catch basins repaired, at $40; total, $158,308.

Brooklyn, N. Y.—Bids will be received until Sept. 24 by J. Edw. Swanstrom, Boro. Pres., for furnishing material and constructing cement concrete sidewalks, requiring in all about 76,457 sq. ft.; also for furnishing material and flagging sidewalks in various parts of the Borough, requiring in all about 61,670 sq. ft. of bluestone flagging.

Pittsburg, Pa.—Bids will be received by W. E. Thompson, Co. Compt., until Oct. 4 for the permanent improvement of certain county roads.

Pittsburg, Pa.—Bids are wanted Oct. 1 for grading and curbing on several streets; for paving with asphalt on portions of numerous streets; for grading, paving and curbing with block stone on portions of numerous streets. Total estimated cost about $425,000. J. Guy McCandless, Dir. Dept. Pub. Wks.

New York, N. Y.—The contract for work on the Grand Boulevard and Concourse, from E. 161st St. to Mosholu Parkway, Boro. of Bronx, was awarded Sept. 4 to the Uvalde Asphalt Co., 1 Bway., their bid submitted Aug. 20 being as follows: Earth excavation, 298,000 cu. yds., 27.5 cts.; rock excavation, 402,000 cu. yds., $1.08; filling, 603,000 cu. yds., .5 cts.; select filling, 14,600 cu. yds., 30 cts.; 18-in. pipe, 1,000 lin. ft. $1.25; 12-in. pipe, 4,000 lin. ft., $1; dry rubble, 12,000 cu. yds., $1.25; masonry in arch, 3,950 cu. yds., $10; ringstones, 2,500 cu. ft., $2; brick work, 2,155 cu. yds., $14; parapet walls, 4,525 cu. ft., $1; coping and corbels, 5,060 cu. ft., $2; coping on parapet, 2,030 cu. ft., $3; pedestals, 1,150 cu. ft., $3; Random range ashlar, 14,100 cu. ft., $6; rubble, 1,860 cu. yds., $4; concrete, 2,100 cu. yds., $4; waterproofing 1,900 sq. yds., 70 cts.; piles, 26,500 lin. ft., 20 cts.; new curb, 39,500 lin. ft., 65.5 cts.; old curb, 3,650 lin. ft., 10 cts.; new flag, 308,800 sq. ft., 22 cts.; old flag, 14,000 sq. ft., 3 cts.; new bridgestone, 24,100 sq. ft., 61 cts.; old bridgestone, 3,550 sq. ft., 10 cts.; macadam, 128,000 sq. yds., 60 cts.; bicycle path, 42,000 sq. yds., 40 cts.; gutters, 33,300 sq. yds., $1.31; lumber, 65,000 ft., B. M., $10; 42-in. circular sewer, 170 lin. ft., $1,520; catch basins, 60, $60 each; guard rail, 4,800 lin. ft., 90 cts.; guard rail 2,900 lin. ft., $1.75; total, $1,011,323.

Buffalo, N. Y.—Bids are wanted Sept. 30 for paving a portion of Sobieski St. Francis G. Ward, Comr. of Pub. Wks.

New York, N. Y.—Bids were opened Sept. 18 by Thos. W. Hynes, Comr. of Dept. of Correction, for building a sidewalk at the City Prison Tombs as follows: John R. Sheehan & Co., $14,500; and P. J. Carlin & Co., $12,000.

Windsor Locks, Conn.—Bids will be received by the Bd. of Selectmen until Sept. 24 for constructing a macadam and telford road in this town. Leslie C. Seymour, 1st Selectman.

Ottawa, Ont.—It is stated that bids are wanted by the Bd. of Pub. Wks. until Sept. 25 for extending Point-aux-Pelee Island wharf. Fred. Gelinas, Secy.; H. A. Gray, Res. Engr., Confederation Life Bldg., Toronto, Ont.

Montreal, Que.—It is stated that bids are wanted Oct. 2 for rebuilding portions and extending Locks 1 and 2 at the entrance of Lachine Canal. L. K. Jones, Secy., Dept. Rys. & Canals, Ottawa, Ont.

The contract for constructing the shore wharf between King Edward and Alexandra piers is reported to have been awarded by the Harbor Comrs. to F. J. Weber for $95,400.

NEW INDUSTRIAL PLANTS.

The American Ochre Co., Cartersville, Ga., is erecting a 40x120-ft. mill, which will have a daily capacity of 20 tons.

The Thomas Mfg. Co., Springfield, O., maker of agricultural implements, expects to erect a new foundry.

The Vigor-o Health Food Co., Ltd., Owosso, Mich., has been incorporated, with a capital of $500,000, and will erect a 3-story and basement, 60x120-ft. factory and a power house 40 ft. square.

The Goodhue, Minn., Milling Co. will erect a 3-story and basement, 32x60-ft mill and a 30x32-ft. engine house, installing a 90-H.-P. Corliss engine and a 100-H.-P. boiler.

The Valley Iron Co., Birmingham, Ala., contemplates the opening of coal and ore mines, the building of coke ovens and the erection of a blast furnace plant near Sulphur Springs and Valley Head. The details have not yet been worked out.

The Globe Iron Works Co., Minneapolis, Minn., contemplates erecting a 45x60-ft. foundry with a 3-ton cupola, and installing a brass foundry.

The Southern Cross-Tie Co. will, about Jan. 1, erect a plant requiring a power plant of about 400 H.-P. Gordon Bryan Mgr., Liverpool & London & Globe Bldg., New Orleans, La.

J. C. Montgomery & Son, Verona, Tenn., will erect a 2-story, 30x50-ft. flour mill. The capacity of the power plant will be 50 H.-P.

The Wellsville, Pa., Mfg. Co. is erecting a 3-story, 100x40-ft. factory to be lighted electrically. The power will be supplied by a 16-H.-P. gasoline engine.

The Duluth, Minn., Brewing & Malt Co. is erecting a stock house, wash house and racking room, the estimated cost of which, with refrigeration, will be about $50,000.

The Vermont Farm Machine Co., Bellows Falls, Vt., has let a contract for a 2-story, 60x170-ft. machine shop with a 17x113-ft. basement.

Wagener Bros., Penn Yan, N. Y., contemplate erecting a 3-story shoe factory, to be about 125x35 ft., and equipped with a power plant of 30 to 50 H.-P.

L. H. Moore, Gentry, Ark., is endeavoring to secure the erection of a cold-storage and ice plant in that place.

Mill No. 1, including the card, spinning and slasher rooms of the Stonewall, Miss., Cotton Mills, was damaged by fire to the amount of about $75,000.

A large Portland cement plant will soon be built near Cumberland, Md., by a company in which Ernest R. and Marion Ackerman, of Plainfield, N. J., are interested.

BUSINESS NOTES.

The Girard, O., Boiler & Mfg. Co. has received a contract from the West St. Louis Construction Co., St. Louis, Mo., for the erection at Kirkwood, Mo., of a steel standpipe of 24 ft diameter and 110 ft. high.

The new plant of the Millers Falls, Mass., Paper Co. will be electrically driven throughout. The contract for the entire equipment, including generators, motors, arc and incandescent lights, etc., has been placed with Sargent, Conant & Co., Boston.

Among contracts recently received by the Otis Elevator Co., for installations in New York, are the following: Hotel Imperial Annex, seven hydraulic and two electric elevators; Blair Building, six hydraulic elevators; Metropolitan Life Insurance Co., 23 high-pressure passenger elevators, four hydraulic freight elevators and two electric passenger elevators for additions to their buildings, and converting 13 passenger elevators so as to be operated at increased pressure. The plant, when complete, will consist of 40 hydraulic elevators operated from one pumping station.

The Chicago office of the Stilwell-Bierce & Smith-Vaile Co. reports the sale of Smith-Vaile triplex pumps for water works and electric light plants at Caldwell, Idaho; Holland and Crystal Falls, Mich.; Little Falls, Minn., and Marseilles, Ill. Also compound steam pumps for Zeeland, Mich.

The Allis-Chalmers Co., Chicago, reports the following among its engine sales for August, the engines being 1890 Reynolds Corliss unless otherwise stated: Armour Institute of Technology, 9 and 18x24-in. cross-compound; Bamberger De Lamar Gold Mines Co., Utah, 22 and 44x48-in. cross-compound and a 28x12-in. Reynolds jet condenser and air pump; Carnegie Steel Co., Pittsburg, repairs for 42 and 60x60-in. blowing engine; Pawling & Harnischfeger, Milwaukee, 18x36-in.; Boyne City, Mich., Lumber Co., 24x48-in.; Kirby Lumber Co., Houston, Tex., 36x60-in.; Interurban Construction Co., Ottumwa, Ia., 18x42-in.; Sloss-Sheffield Steel & Iron Co., Birmingham, Ala., three vertical standard long crosshead 44 and 84x60-in. blowing engines; Calumet & Arizona Mining Co., Douglas, Ariz., 14 and 28x36-in. tandem compound, and a left hand low pressure side 40 and 44x48-in. Reynolds Corliss condensing blowing engine; National Lead Co., New York, 18 and 32x36 tandem compound; Miner Hillard Milling Co., Wilkesbarre, Pa., 20x42-in. girder frame; Larson & Orwell, Clarkfield, Minn., 10x30-in. girder frame; Oregon Smelting & Refining Co., Sampter, Ore., 16x36-in. girder frame; Iroquois Iron Co., Chicago, 42 and 87x60-in. vertical long crosshead blowing engine; Shattuck Bros., Sparta, Wis., 8x24-in. girder frame; City of Henderson, Ky., 24x48-in.; Deaver, Colo., Tramway Power Co., 32 and 68x60-in. and 30 and 64x48-in. cross-compound condensing; Detroit, Mich., Copper & Brass Rolling Mills, 26x48-in.; Southern Electric Light & Power Co., Philadelphia, 42 and 86x60-in. combined horizontal and vertical duplex compound condensing; Horseshoe Mining Co., Deadwood, S. D., 14x42-in., and 16 and 24x42-in. tandem compound; E. H. Dyer & Co., Cleveland, O., 12x36-in. girder frame; Sanitary District of Chicago, for 39th St. Pumping Station, two steam and two water ends for vertical triple expansion pumping engine and a centrifugal drainage pump; City of Allegheny, Pa., a steam and a water end for a 5,000,000-gal. vertical triple pumping engine; Penna. R. R. Co., two Sederholm boilers, 384 H.-P.

The Ball Engine Co., Erie, Pa., reports the following among its recent orders: An additional unit, this being the third, for the Security Building, St. Louis, Mo.; three 400-H.-P. units for the Lewis Block, Pittsburg; two engines to Port Antonio, Jamaica, and one to Japan.

James W. Copeland, 934 Equitable Bldg., Denver, Colo., has been appointed sole agent for Colorado for the Scaife and We-Fu-Go water softening and purifying systems, manufactured by Wm. B. Scaife & Sons Co., Pittsburg, Pa.

The Pittsburgh Gage & Supply Co. has received contracts for two 250-H.-P. water-tube boilers for the Ward-Mackey Co., Pittsburg, and a White-Star filtering system for the power house of the New York & Stamford St. Ry. Co., Port Chester, N. Y.

G. M. Gest, 277 Broadway, New York, has recently secured the contract for the conduit system, amounting to over 200,000 ft., for the Schenectady, N. Y., Ry. Co.

The following firms were represented with exhibits at the annual meeting of the New England Water Works Association at Boston: Jenkins Bros., 17 Pearl St., Boston; Manning, Maxwell & Moore, 85 Liberty St., New York, representing the Hayden & Derby Mfg. Co., Ashcroft Mfg. Co., Consolidated Safety Valve Co., and Hancock Inspirator Co.; Sweet & Doyle, 238 Franklin St., Boston; Lamb & Ritchie, Cambridgeport, Mass.; Garlock Packing Co., 12 Pearl St., Boston; H. Mueller Mfg. Co., represented by Sumner & Goodwin, 287 Congress St., Boston; Union Water Meter Co., Worcester, Mass.; Pittsburg Meter Co., East Pittsburg, Pa.; Thomson Meter Co., Brooklyn, N. Y.; Hersey Mfg. Co., Boston; Harold L. Bond & Co., 140 Pearl St., Boston; Lead Lined Iron Pipe Co., Wakefield, Mass.; Walworth Mfg. Co., Boston; N. W. Stearns, 308 Warren St., Roxbury, Mass.; Charles A. Claflin & Co., 188 Franklin St., Boston, representing Nelson Valve Co., Wyndmoor, Pa.; Michigan Lubricator Co., Detroit, Mich.; Crandall Packing Co., Palmyra, N. Y., and Hills-McCanna Co., Chicago, Ill.; Stilwell-Bierce and Smith-Vaile Co., Dayton, O.; A. W. Chesterton & Co., 49 India St., Boston; the Wells Light Mfg. Co., 44 Washington St., New York; Perrin, Seamans & Co., 57 Oliver St., Boston; Coffin Valve Co., Neponset, Mass.; A. P. Smith Mfg. Co., Newark, N. J., and Frank E. Merrill, Somerville, Mass.

The following industrial establishments have recently purchased electrical apparatus from the Westinghouse Elec. & Mfg. Co.: India Rubber & Gutta Percha Insulating Co., which is installing 1, 5, 10 and 15-H.-P. alternating-current motors at Yonkers, N. Y., to replace isolated steam engines; Pennsylvania Salt Mfg. Co., which has purchased a number of direct-current motors for its plant at Wyandotte, Mich., and the Stanley Rule & Level Co., New Britain, Conn., which has purchased a 375-Kw. 500-volt direct-current generator to be operated from a marine-type Westinghouse engine for electric driving of the works.

The "Hydro-Carbon" system of fuel combustion, controlled by the Steam Boiler Equipment Co., of New York, was exhibited at the recent convention of the National Association of Stationary Engineers in Boston. Two boilers of the engineering building at the Massachusetts Institute of Technology were equipped with the system to demonstrate its ability to prevent smoke with bituminous coal, the ease of firing and the maintenance of a steady steam pressure with economy in coal consumption

TABLE OF LEADING ARTICLES.

Unreasonable Contract Requirements by the Government.—II. 289
The Break in the Utica Reservoir. (Illustrated).. 290
A List of Failures of American Dams.... 290
Rapid Base Line Measurement for the Ninety-eighth Meridian Triangulation. (Illustrated)... 293
An Unusual Water Supply Plant.... 296
The Power Plant of the Stecher Lithographic Company, Rochester, N. Y. (Illustrated)...... 297
Complicated Underpinning. (Illustrated)....... 299
Experiments with Wet, Medium and Dry Concrete 301
Sanitary Progress 302
Unreasonable Contract Requirements by the Government 303
The High-Level Bridge, Newcastle. (Illustrated). 303
A Double Water Tower.... 304
Book Notes.... 304

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Unreasonable Contract Requirements by the Government.—II.

In the general criticism of the specifications of the Bureau of Yards and Docks of the Navy Department, for the concrete and granite dry dock to be built at Charleston, S. C., in the Engineering Record of a week ago, attention was called to the arbitrary and unreasonable provisions of paragraph 3, in which the contractor is made responsible for the "Omissions and misdescriptions" of the engineering authority of the department. It is again well enough to note that such omissions and misdescriptions "shall not operate to release the contractor from supplying all such materials and performing such work, but the same shall be fully and properly supplied and performed in the same manner as if fully and correctly shown, described and required in and by the contract, and without expense to the United States in addition to the contract price." In view of our previous general criticism this excerpt probably speaks with sufficient effectiveness for itself as a vicious method of evading responsibility both as to authorship and consequences and as an effort to compel a contractor to gamble on the exigencies of a contract.

It might naturally be supposed that a contractor should within reasonable limits direct his own force and plant in the proper performance of his work in accordance with the specifications, but in paragraph 5 of the General Provisions of these specifications the "civil engineer in charge of the work or other authorized representative, shall at all times have full control and direction of all work under the contract, . . ." This provision taken literally is drastic and unqualified. Only by sufferance of the department's engineering representative may the contractor direct and control his work. This would be bad enough if the general character of the specifications conveyed the impression of effective capacity and self-reliance on the part of the engineering personnel of the office of the Chief of the Bureau; but other paragraphs of the specifications like 3, 25 and 37 would appear to indicate that the responsible engineer of that office entertained a decided distrust of the engineering administration of the work covered by the contract, at least so far as plans and specifications are concerned. Taking the specifications as a whole one might venture to suppose it to be the part of wisdom to permit an efficient and reputable contractor to conduct his own work with but a modest and circumspect general direction from the office of the Chief of the Bureau. On well managed works the engineer must certainly exercise a close general supervision and be intimately in contact with every detail of the work so as to secure with certainty every desired result, but to assume full control and direction of all work at all times is grossly unbusiness-like and unjust to the contractor. As a matter of fact the provision would be without any effect, or otherwise it would repel every contractor who had efficiency enough to be permitted to bid on government work.

The preceding remarkable features of the specifications for a great government work are but the beginning of a list of such length that it will not be attempted to name them all, but those disclosed by reading paragraphs 7 and 15 should not be omitted. In paragraph 7 the civil engineer in charge is empowered to discharge "immediately" "any person employed upon the work" should it "appear" to him that such person "is incompetent, careless, reckless or disorderly, etc., etc." Just why it will be objectionable to discharge a man on ascertainment of fact instead of acting on appearances is not clear. Again, under the provisions of paragraph 15, if it should "appear" to the civil engineer in charge "that the work is not likely to be completed within the time allowed," "the Chief of the Bureau of Yards and Docks . . . may, in his discretion, declare the contract null and void" on report of the civil engineer to him as to those appearances. This provision is unreasonable and arbitrary and its enforcement could accomplish no good purpose. It should not be the policy of the United States government to subject those whom it engages to execute great contracts, to conditions so probable to lead to loss as to make it unwise to bid a reasonable price for the work to be done. No contractor governed by the first glimmerings of good judgment could contemplate for a moment bidding for work like that of the Charleston Dock, involving all the hazardous uncertainties of subaqueous conditions, with such provisions of a proposed contract hanging over his work, for anything less than an extravagant amount. The result of such a high-handed procedure as the annulling of a contract on mere appearances presenting themselves to the mind of a subordinate or of even a chief, would inevitably result in serious losses to a contractor in many stages of any work, and every bidder under such circumstances is forced by the specifications to add to his reasonable profits a large enough sum to cover the contingency of an arbitrary, if not incompetent, engineer. It cannot be supposed for a moment that the Navy Department deliberately intends to serve notice to that effect on bidders for its great contracts, and yet that is precisely the effect of these specifications.

There is a provision in paragraph 24 which seems to indicate that the Chief of the Bureau expects the contractor to design material parts of all portions of the work as the provision reads "For all portions of the work the contractor shall submit the necessary detail plans to the civil engineer in charge for approval." If the department's engineers are to design the work it is difficult to understand why the contractor should submit to the department's engineer detail plans for all portions of the work. It would be more natural to suppose that the submission should be in the other direction. If the engineer is designing a work to meet the requirements of his specifications in an efficient manner and for which he is to be responsible he cannot justify himself in shifting to the contractor the duty of preparing plans, verifying dimensions and making final measurements, but at the same time permitting no deviations from specified dimensions, even in case of error, until the engineer has certified to those deviations on the ground that his own figures are in error and generally unreliable. A more remarkable confession of essential incompetence and unreliability on the part of a responsible engineer than that found in paragraphs 24 and 25 is seldom seen.

It would appear from paragraph 32 that even after the dock has been completed and after "the structures and all work included under the contract" has been tested by a board of officers appointed by the Secretary of the Navy, the Chief of the Bureau of Yards and Docks will still be unable to decide whether the dock shall be accepted, although if the test prove to be satisfactory the full contract price shall be paid to the contractor, as it is provided that he (the Chief of the Bureau) may continue to "test the dry dock and appurtenances under any working conditions" for a further period of six months before the contractor and his bondsmen are to be released from responsibility. If after six months of such testing no defects appear that release will be granted, but if they do appear they are to be made good by the contractor without further compensation. If an engineering force is not sufficiently qualified or competent to determine whether material and workmanship are satisfactory during the progress of work it would seem highly reasonable and business-like to substitute another sufficiently qualified and efficient to determine the character of the work being supervised, rather than to attempt to discover and repair errors after they have been incorporated in, and possibly concealed by, a completed structure.

The remaining technical details of the specifications will be treated in a future issue of the Engineering Record.

EXTRACTS FROM SPECIFICATIONS REFERRED TO ABOVE.

3. Omissions and misdescriptions.—The omission from the contract, or from the plans, specification, or other papers attached thereto and forming a part thereof of any work or materials required to secure the result set forth in paragraph 1, or the misdescription of any details of work, the proper performance of which is necessary to carry out fully the intention above expressed, shall not operate to release the contractor from supplying all such materials and performing such work, but the same shall be fully and properly supplied and performed in the same manner as if fully and correctly shown, described, and required in and by the contract, and without expense to the United States in addition to the contract price.

5. Control of work.—The United States, by its civil engineer in charge of the work or other authorized representative, shall at all times have full control and direction of all work under the contract, and all questions, disputes, or differences as to any part or detail thereof shall be decided by such civil engineer or representative, subject only to appeal to the Chief of the Bureau of Yards and Docks.

7. Employees.—The contractor shall employ only competent, careful, orderly persons upon the work, and if, at any time, it shall appear to the civil engineer in charge that any person employed upon the work is incompetent, careless, reckless, or disorderly, or disobeys or evades orders or instructions, or shirks his duty, such person shall be immediately discharged from and not again employed upon the work.

15. Progress of work.—If at any time the progress of the work shall, in the opinion of the civil engineer in charge, appear to have been such as to indicate that the work is not likely to be completed within the time allowed, he shall report such opinion to the Chief of the Bureau of Yards and Docks, who may, in his discretion, declare the contract null and void, without prejudice to the right of the United States to recover for defaults therein or violations thereof.

24. Plans.—Twelve sheets of plans numbered 1 to 12, inclusive, dated July, 1902, accompany this specification. These plans and their principal subject matter are as follows:

Sheet 1.—Borings and general location and layout.
Sheet 2.—Cross-sections.

Sheet 3.—Plan and longitudinal section on center line. Head end.
Sheet 4.—Plan and longitudinal section on center line. Entrance end.
Sheet 5.—Wing and quay walls and track details.
Sheet 6.—Details of guard stanchions, railing, and chain.
Sheet 7.—Details of capstans, bollards, cleats, shore fastenings, ringbolts, etc.
Sheet 8.—Details of culvert, main conduit, and crane track.
Sheet 9.—Details of granite masonry.
Sheet 10.—Details of granite masonry.
Sheet 11.—Details of bilge-block pulleys.
Sheet 12.—Details of blocks and fittings.

This specification and the plans accompanying it shall be considered as supplementary one to the other, so that materials and workmanship shown, called for, or implied by the one and not by the other shall be supplied and worked into place the same as though specifically called for by both. All detail plans that may be furnished subsequently in further amplification, as well as all instructions given by the civil engineer in charge that may be necessary to more fully indicate the intention of the specification and the above-mentioned plans, shall be followed and considered as though forming a part of the original contract. For all portions of the work the contractor shall submit the necessary detail plans to the civil engineer in charge for approval, unless otherwise directed by him, before proceeding with the work. These details shall conform to the letter and spirit of the specification, to any supplementary data and instructions, and to the general and detail plans already furnished the contractor. Plans shall be submitted to the civil engineer in charge in the form of tracings on cloth of Bureau of Yards and Docks standard sizes. These will be returned to the contractor, either with blue prints of same stamped "approved," or "to be revised" as noted on the tracings. In the latter case the necessary corrections shall be made and the revised drawings submitted before proceeding with the work. Approval of plans will be of a general nature and will not relieve the contractor from errors or omissions that may exist therein.

25. Checking plans and dimensions; lines and levels. —The contractor shall check all plans furnished him immediately upon their receipt and promptly notify the civil engineer in charge of any discrepancies discovered therein. Figures marked on plans shall, in general, be followed in preference to scale measurements; but the contractor shall compare all plans and verify the figures before laying out the work, and will be held responsible for any errors therein that thereby might have been avoided. Large-scale plans shall, in general, govern small-scale plans. In all cases where dimensions are governed by conditions already established the contractor must depend entirely upon measurements taken by himself, scaled or figured dimensions to the contrary notwithstanding; but no deviation from the specified dimensions will be allowed unless authorized by the civil engineer in charge. The contractor will be held responsible for the lines and levels of his work, and he must combine all materials properly.

32. Test of completed structures.—After the dry dock and all appurtenances relating thereto, required by the contract, are complete in all particulars, a board of officers appointed by the Secretary of the Navy for the purpose, will examine and test the structures and all work included under the contract. All expense of such examination and test will be borne by the Government. After the board has reported that all work called for by the contract has been completed in every particular, according to the true intent and meaning of the specification, plans, and contract, and after the report has been approved by the Chief of the Bureau of Yards and Docks, the contractor will be paid the remainder of the contract price. For a further period of six months after the approval of the report of the above board by the Chief of the Bureau of Yards and Docks, the Government may test the dry dock and appurtenances under any working conditions which it sees fit; and, if at the end of that time, no bad workmanship, weakness, or other defect due to the fault of the contractor shall appear, the work will be accepted and the contractor and his bondsmen will be released from further responsibility; if such defects do appear, they shall be made good by the contractor without additional compensation.

37. Borings.—Sheet 1 contains a record of borings made at various places on the Government property. This record is given for the information of bidders; however, the Government does not guarantee it to be correct in all particulars, or that the conditions will be found uniform, and it will not be responsible for any additional cost of work due to any variation from the same that may be found during the progress of the work.

Lignite is used for Fuel at the Elektrochemische Werke at Bitterfeld, Germany, where there are 21 water-tube boilers supplying steam engines of 5,400 total horse-power. It is carried directly from the mines into the coal bunkers at one-third the cost of coal.

The Break in the Utica Reservoir.

In 1873-74 the old Utica, N. Y., Water-Works Company built an earthen dam under the direction of the late Thomas Hopper, president and everything else of the corporation, and this dam subsequently formed a basin known as the Savage reservoir. The construction of the dam, like that of most one-man works, has always been considerable of a mystery, but it served its purpose satisfactorily for many years and it was not until September 13 that any apprehension was felt for its safety. Early on the morning of that day a slice of the embankment about three-quarters of the way to the top and 5 feet thick slid down the slope. The engineer and general manager of the company now owning the water-works of the city, Mr. William S. Bacot, M. Am. Soc. C. E., was at once notified of this occurrence. As soon as he inspected the slide and noticed the dampness of the embankment, he ordered every outlet from the reservoir to be opened as wide as possible; there were two spillways, a 20-inch blow-off pipe and a 20-inch discharge pipe, which were available for this purpose. By the end of the day the water had been drawn down 3½ feet and by Sunday night 6½ feet. But on Sunday morning, in spite of the emptying of the reservoir, another slip occurred and cracks opened in the embankment. Everybody lower down in the valley was notified of the danger, and so when the dam finally went out on the afternoon of September 16, not only was there no one in the path of the flood, but there was fortunately a large gathering of spectators expectantly awaiting the disaster. On this account definite information is available concerning the manner in which the accident took place. In the accompanying engraving of the break in the reservoir before the completion of the washout, it may be observed that a dozen people are standing on the crest of the dam while the water is still passing through the crevasse within 75 feet of them. Except in the case of the Austin dam, it is probable that no recent failure has occurred under conditions that enable such definite information to be given.

As a matter of fact, there is hardly anything to be said concerning the failure that an engineer cannot deduce from the two engravings. The dam was about 70 feet high, 275 feet wide at the base and 20 feet at the top. It is evident from the engraving that the slopes were too great, while the sides of the crevasse afford excellent instruction concerning materials not suitable for high reservoir dams. Water having once percolated through such a structure would inevitably destroy it. Just how the first percolation began cannot be stated, but the fact that muskrats were seen in the pool left inside the basin suggests that their burrowing may have started the trouble. The accidents they have caused in sections of the Erie Canal is well known.

Water first came through the dam near the crest in small jets. These streams worked downward faster than upward and for a time there was a little earth arch over the opening. This soon fell, however, and the water cut a V-shape notch in the embankment which finally had the shape shown in one of the illustrations. No official account of the disaster has yet been given out by the owners of the reservoir.

Owing to the foresight of Mr. Bacot there was no loss of life, as before stated, and, strangely enough, not a large amount of damage to property. The largest loser is the company, which has not yet determined what will be done with the dam. If it is raised again, it will have to be rebuilt entirely from the bottom up.

BREAK IN RESERVOIR BEFORE COMPLETION OF WASHOUT.

A List of Failures of American Dams.

From the Presidential Address of W. R. Hill, M. Am. Soc. C. E., before the American Water-Works Association.

A dam at Middlefield, Mass., failed on April 21, 1901. It was of earth faced with rubble walls and with two lines of sheet piling driven 15 feet apart with the space between them filled with puddle. The dam was 500 feet long, 20 feet high, 50 feet thick at the base and 30 feet at top. The failure was caused by water flowing over the crest of the dam. Four highway bridges were carried away. (Eng. Rec., May 4, 1901.)

A dam at Victor, Col., failed on May 19, 1901. It was of earth, 430 feet long and 25 feet high. The reservoir held 70,000,000 gallons of water, all of which escaped. The cause of the failure was due to an inadequate spillway. (Eng. Rec., June 8, 1901.)

A reservoir at Lebanon, O., having an area of 40 acres failed on July 10, 1882. The embankment, which was 30 feet high, was destroyed by water flowing over its crest. Five bridges and many houses valued at about $50,000 were swept away.

A large storage reservoir near Lima, Mont., was suddenly emptied by the washing out of the spillway in May, 1894, the dam being left intact. The lower end of the spillway had a fall of 30 to 40 feet, and a flood rapidly cut a huge channel back from the fall into the reservoir. The reservoir was said to have been 15 miles long and 1 mile wide.

A dam of a reservoir near Avoca, Pa., failed on May 25, 1894, the cause of failure being insufficient spillway. The capacity of the reservoir was 350,000 gallons.

The Spartansburg dam, near Oil City, Pa., failed June 4, 1892. It was 180 feet long and 10 feet high, and impounded a lake 1½ miles long and 1 mile wide. The dam was of earth and rock with center sheet piling for 150 feet. The balance, or a length of 30 feet, was without piling. It was this part of the dam that washed out. There was no waste weir other than a small flume, and the failure was caused by water running over the crest of the dam.

Melzingah reservoirs Nos. 1 and 2 of the Matteawan and Fishkill (N. Y.) Water Company failed on July 14, 1897. Each reservoir had a capacity of 6,000,000 gallons, and was formed by dams built across the same stream. Both dams were of earth with masonry core wall. The upper dam, which was 250 feet long and 30 feet high, failed first. The lower dam was 220 feet long and 24 feet high. Seven lives were lost and $30,000 worth of property was destroyed. The cause of failure was a freshet flowing over the crest of both dams. (Eng. Rec., July 17, 1897).

The city reservoir at Grand Rapids, Mich., failed July 2, 1900. The embankment was of earth with clay puddle core, lined on the inside with rubble masonry in cement, one foot thick, resting on a layer of concrete one foot thick. The bank was 12 feet wide on top, the inner slope was 1½ to 1, and the outer slope was 2 to 1. The capacity of the reservoir was 6,000,000 gallons, with water 25 feet deep. The failure was caused by water flowing over the top of the bank, and the damage due to it amounted to about $100,000. (Eng. Rec., July 14, 1900.)

The Walnut Grove dam on the Hassayampa River, 30 miles south of Prescott, Arizona, failed on February 22, 1890. It was 110 feet high from the rock foundation to the coping, 400 feet long, 140 feet thick at the base and 10 feet at the top. It was a rock-filled dam with walls on both faces made of large granite blocks of dry masonry, with a timber lining on the water side. The walls were 20 feet thick at the bottom and 5 feet at the top. The waste weir was only 26 feet wide, while the area of the watershed was about 500 square miles. The reservoir had an area of about 1,000 acres. The cause of failure was supposed to be water flowing over the crest of the dam. About 150 lives were lost, and the damage to the dam and the property destroyed was estimated to be about $800,000.

The most appalling catastrophe and terrible lesson ever given by faulty construction of a dam in the history of this country occurred on May 31, 1889, by the breaking of the dam across the south fork of the Conemaugh River above Johnstown, Pa. The dam was constructed in 1852 for a reservoir as a feeder for the Pennsylvania Canal. In 1857 it was abandoned, and in July, 1862, a culvert in the embankment gave way owing to some imperfection of the foundation. The depth of water at that time was about 40 feet, all of which was discharged with the exception of about 8 feet, but owing to the substantial character of the dam the leakage was slow and but little damage was done. From 1862 to 1880 the reservoir was empty, and in the latter year the dam was reconstructed to a height of 2 to 3 feet lower than originally. However, a fatal mistake was made in leaving a low place or sag in the middle of the dam. Another mistake made was the obstruction of the spillway with an iron grating placed to retain the fish in the reservoir. The spillway should have been lowered because of the lowering of the crest of the dam, and enlarged because of the obstruction. On the fatal day the water rose and flowed over the crest of the dam because the spillway was too small to discharge the water, and in a short time 400 feet of the dam washed away, dissolving like a phantom. The loss of life was variously estimated at from 4,000 to 10,000, and the damage to property amounted to about $9,000,000. The reservoir had an area of about 400 acres, an average depth of 30 feet, and a capacity of about 5,000,000,000 gallons. The area of the watershed was about 60 square miles. The dam was constructed entirely of clayey earth, 72 feet high, 20 feet wide on top with an inside slope of 2 to 1, and an outside slope of 1½ to 1. The inside slope was protected with a light riprap. (Eng. Rec., June 8 and 15, 1889.)

THE FINAL SHAPE OF THE CREVASSE.

Many failures have been caused by water leaking along pipes laid through embankments. To prevent such leakage the pipes should be laid in rubble or concrete masonry surrounded with puddle. Among instances of failures due to such leakage may be mentioned:

The dam of Rock Springs Water Works reservoir, above Blairtown, Wyo., burst February 2, 1888. The cause of the failure was water leaking around a pipe laid through the dam.

A reservoir bank at Wilmington, Del., failed in October, 1900. It was of earth lined with clay and faced with brick. It was 10 feet high where the break started. The cause of the failure was supposed to be due to leakage of water along pipes laid through the bank. (Eng. Rec., Oct. 20, 1900.)

A reservoir at East Liverpool, O., failed October 13, 1901, when it was being filled for the first time. It was lined with 18 inches of concrete laid on 27 inches of puddled clay. It had a capacity of 12,000,000 gallons. The break occurred over a pipe laid through the embankment. (Eng. Rec., Nov. 2, 1901.)

The embankment of a reservoir at Ansonia, Conn., broke out November 3, 1894, making a gap 200 feet long and 35 feet deep and washing out about 200 feet of the roadbed of the New York, New Haven and Hartford Railroad. The failure was caused by water percolating along the waste pipe laid through the embankment. (Eng. Rec., Nov. 10, 1894.)

A dam of a reservoir at Gunnison, Cal., burst on May 21, 1890. The reservoir was 5 miles long, about 1½ miles wide and 20 feet deep. The accident was caused by leaks along the drain pipe.

An earthen embankment with a masonry face wall, at Staffordville, Conn., gave way on March 27, 1877. The embankment was 26 feet high and 150 feet long, and the wall was 10 feet thick at the base and 4 feet at the top. The failure was due to water leaking along the waste pipe laid through the embankment. Some lives were lost, and the damage to buildings, bridges, etc., amounted to about $300,000.

At Lancaster, Pa., a reservoir failed on October 14, 1894, while first being filled. The embankment was of earth with puddle center. The reservoir had a capacity of 15,000,000 gallons with the water 21 feet deep. The water was seen to gush out from the outer slope of the embankment and in an instant a break 30 feet in width was made, through which the reservoir rapidly emptied. The reservoir was lined with clay, protected by a coating of cement mortar, then a brick paving finished with grout. The failure was due to water leaking along the outlet pipe. (Eng. Rec., Oct. 27, Dec. 8, 1894.)

The embankment of a 20,000,000 gallon distributor reservoir at Portland, Me., failed on August 6, 1893, after having been in use four years. The embankment was without a core wall and was 10 feet wide on top, 45 feet high, and the slopes were 1½ to 1 on each side. Six feet of the inner slope was puddled clay and 6 inches of broken stone, upon which was laid granite paving blocks 8 inches thick. A drain pipe was laid through the natural surface under the embankment, and an overflow pipe was laid over it sloping downward through the embankment. The break occurred over these pipes. The cause of the failure was said to be either the action of frost, or the light embankment, or water following the pipes. Much damage was done and four lives lost. (Eng. Rec., Aug. 19, 1893.)

The dam of the Spring Lake Reservoir near Fiskville, R. I., failed August 25, 1889. The reservoir had a capacity of 35,000,000 gallons. The dam was made of clay and gravel and was 825 feet long, 18 feet high, 8 feet wide on the top and 35 feet wide on the bottom. The outside slope was retained by a stone wall, and the inner slope was paved with stone. The portion washed away was just above the waste pipe. Property valued at about $25,000 was destroyed, and three lives were lost. (Eng. Rec., Aug. 31, 1889.)

Water also displays a tendency to following along masonry laid in embankment, as is indicated in the following instances:

The Lynde Brook reservoir embankment of the water works of Worcester, Mass., failed on March 29, 1876. It was of earth, paved on the inside with rubble masonry on a slope of two to one. It was 287 feet long, 27 feet high and 25 feet wide on top. The embankment was originally built in 1854, was enlarged and modified in 1870, when it was made 19 feet higher, and a heavy face wall of masonry was added. The reservoir had a capacity of 776,000,000 gallons. Water leaked around a culvert that passed through the base of the embankment, making a breach 200 feet long and destroying property valued at nearly $1,000,000.

Many annoying failures have been caused by the bottoms of reservoirs settling and breaking, due to the weight of the water, thus giving it an opportunity to escape through the loose underlying material. To obviate this difficulty the outer walls of the reservoir if possible should be carried down to solid rock or other stable impervious material. If such material cannot be found, the greatest care should be exercised in lining both the bottom and sides of the reservoir.

Among the most striking cases of such failures may be mentioned the following:

The bottom of the city reservoir at Roanoke, Va., caved in on Nov. 10, 1888, causing a loss of about $15,000.

The puddle bottom of a double reservoir at Knoxville, Tenn., failed on May 31, 1883.

A reservoir on Conshohocken Hill, near Philadelphia, Pa., with a capacity of about 1,000,000 gallons, was lined with about 18 inches of clay, upon which was laid a brick paving in cement. The bottom lining broke away in 1873 and was repaired. It failed again in the years 1876, 1879 and 1886.

The concrete lining of a reservoir at Portland, Ore., cracked badly before water was let in. The concrete was 5 to 6 inches in thickness with ⅜-inch square twisted rods bedded in the concrete every two feet in each direction. On Dec. 13, 1894, water was turned into the reservoir and serious leaks and further cracks appeared in the bottom lining. (Eng. Rec., Feb. 2, 1895.)

The Milburn storage reservoir of Brooklyn, N. Y., was completed in 1893 and has never been in use. In August of that year 43,500,000 gallons of water were pumped into it, all of which leaked out through the bottom in a period of ten days. The puddle bottom of the reservoir was considered to have been improperly put in, although it was generally of good material. Experts have recommended that the entire bottom of 44 acres be repuddled, though nothing has yet been done in regard to their recommendations. (Eng. Rec., April 28, 1894.)

A leak in one of the basins of the Roxborough reservoir of the Philadelphia Water Works was discovered in 1891, after the reservoir had been in use nearly a year. A depression was found in the embankment about 3 feet above the bottom. Underneath the brick lining the clay had been washed away, and below there was a fissure in the rock 6 to 10 inches in width. Through this fissure the water escaped, coming to the surface 1,200 feet away. Water was first pumped into this reservoir on September 21, 1893. When it had been filled to a depth of 20 feet an increased flow was detected in a spring nearby. The leak was not located for nearly a year after. An expenditure of about $140,000 was required to reconstruct the interior lining. (Eng. Rec., Jan. 12, 1895.)

The Queen Lane reservoir of Philadelphia was practically completed on October 1, 1894. Later it was filled to a depth of 10 feet and developed leaks at many points. The bottom was lined with 4 inches of concrete and was upon a layer of clay puddle 2 feet in thickness, which was built up in layers, rolled and watered. The rock underlying is gneiss and mica, and the upper portion of this is more or less disintegrated. The cost of reconstructing the interior lining of the reservoir was about $275,000. (Eng. Rec., Dec. 22, 1894.)

Many disastrous failures have been caused by embankments and walls being undermined where they were built upon porous or yielding material. The general rule should be to build the structure upon a firm and impervious foundation in all cases if at all possible.

The dam of the Light and Power Co., at Tacoma, Wash., was undermined in December, 1892. It was built of timber and was about 120 feet long, holding back a depth of 17 feet of water. (Eng. Rec., Jan. 7, 1893.)

The Housatonic dam, near Birmingham, Conn., failed in the latter part of January, 1891. It is a curved masonry dam, 636 feet long, 40 feet high, 25 feet thick at the base and 8 feet at coping, costing $264,000. In 1869, while under construction, a heavy freshet carried away 160 feet of the partly finished work and scoured out a cavity 20 feet deep in the river bed. This cavity was filled with loose rock, and a timber apron, filled with concrete, was placed upon it. Twenty-two years afterwards 250 feet of the dam was swept away by the undermining of the loose rock under the timber apron.

A break in the reservoir embankment at Dallas, Texas, occurred in June, 1891. The embankment was of clay without a core wall, the inner slope paved with brick in cement, set on edge upon 3 inches of gravel. It was 29 feet high and 12 feet wide on top, with an inner slope of 2 to 1. The reservoir had a capacity of 140,000,000 gallons. A large part of the bank sank vertically, due as was thought to quicksand beneath the foundation. The settlement was over 300 feet in length and extended from the toe of the outer slope to within 5 feet of the top of the inner slope. The brick and cement lining was cracked in an almost straight line at 11 feet from the top, and from this line to the top of the embankment there was a slight settlement.

The Angel's dam, Calaveras County, Cal., was undermined on April 10, 1895. This dam, costing $52,000, was of rubble stone masonry, 400 feet long and 52 feet high. It was 35 feet thick at the base, and at a height of 20 feet the thickness was abruptly reduced from 21 to 13 feet. At the top it was three feet thick. The upstream face of the dam was vertical. During the time of construction workmen were engaged in digging a hole near the wall, and the foreman said "they were trying to dig out a cotton wood stump, but the blamed roots ran clear under the wall and he could not get them out."

The Mill River reservoir dam, at Williamsburgh, Mass., burst on May 16, 1874. The dam was of earth with a masonry core wall. It was 600 feet long, 43 feet high and 16 feet wide on top with slopes of 1½ to 1 on both sides. The core wall was 2 feet thick at top and 5 feet 9 inches at bottom. It was laid in a trench on an earth foundation 3 feet below the natural surface. The reservoir had an area of 114 acres and an average depth of 20 feet. Water found its way under the core wall and destroyed the embankment. The reservoir was suddenly emptied into a narrow valley, causing a loss of 140 lives and the destruction of about $1,000,000 worth of property.

The following failures are said to be due to poor workmanship or faulty designs:

The dividing wall of a reservoir at Little Rock, Ark., burst on Nov. 2, 1887. The wall was of rubble masonry 36 feet high, 12½ feet thick at the bottom and 7 feet at the top. The reservoir held 7,000,000 gallons of water in each basin. The wall is said to have been poorly constructed.

The Mud Pond dam, near East Lee, Mass., failed on April 20, 1886. This dam was of earth with a dry boulder wall on the downstream side. It was 325 feet long, 15 feet high, 28 feet thick at the base and 6 feet at top and said to have been poorly constructed. Seven lives were lost, and the damage to property amounted to about $250,000.

To increase the capacity of a reservoir about 100 feet square on Vernon Heights, Oakland, Cal., a wall of asphalt concrete was built around it. The wall was 8 feet high and only two feet thick at the base and one foot at the top. It had no depth in the soil and was built partly on made ground. It failed October 20, 1896.

A reservoir at Scranton, Pa., gave way on October 10, 1895. The walls were of rubble with dressed granite faces, filled with concrete and strengthened with stone buttresses about 24 feet apart. The wall was 10 feet thick at base, and the depth of water was 20 feet. About 120 feet of the wall gave way after having been in use ten years.

Two new reservoirs at Nebraska City, Neb., failed on April 10, 1890, shortly after being put into use. The banks were of earth 8 feet wide on top with slopes of 1 to 1 inside and 1½ to 1 outside. The depth of water was 17 feet. The soil was very porous, and to prevent the percolation of water the embankments and bottom of the reservoir were lined with 2-inch plank, which was covered with about a foot of earth.

A timber dam at Northfield, Vt., failed August 27, 1890. It was 100 feet long and 25 feet high at the deepest point. It was built of single layers of 12-inch by 12-inch hemlock timbers, 10 feet long, simply placed one above the other and drift bolted together. The dam was roughly in the form of an arch of 40 feet radius, and each set of timbers formed a 10-foot chord of the arch. They were not fastened together at the ends by spiking or by any vertical binding pieces. The only additional part to the dam, besides the 12-inch timbers, was an interior vertical lining of 3-inch planks, making the dam only 15 inches in thickness. In placing the planks the end joints were not broken. The dam stood the test of being filled twice within a period of 8 days before it failed. It seems hardly necessary to state that no engineer was employed in charge of the construction.

In several instances the weakness in construction has developed through the force of ice.

The Kinsman Street reservoir at Cleveland, O., failed in December, 1886, because of ice pressure and the sudden drawing off of water.

A concrete dam of the Water Power Company at Des Moines, Iowa, failed in March,

1893. Cause of failure due to ice, undermining and faulty construction. (Eng. Rec., April 15, 1893.)

In the year 1896 a reservoir at Montreal, Canada, of a capacity of 42,000,000 gallons, leaked at the rate of 350,000 gallons per day. The leakage is believed to have been caused by the ice near the high water line. The reservoir was formed by a masonry wall, backed first with puddle and then with an earth and stone embankment.

The upper dam of the St. Anthony's Falls Water Power Company at Minneapolis, Minn., failed on April 30, 1899. It was of coursed ashlar sandstone masonry, 530 feet long, 18 feet high, 12 feet thick at the base and 5 feet 1½ inches at top. The damage to the dam, which amounted to about $25,000, is said to have been caused by ice pressure. (Eng. Rec., May 13, 1899.)

The following structures failed for miscellaneous or unknown reasons:

Dam No. 2 of the Mahanoy City, Pa., Water Company gave way June 17, 1892. It was of puddled clay without a core wall. The inner slope was paved and the outer slope covered with large stones. It was 130 feet thick at the bottom and 25 feet at the top. The depth of water was 18 feet and the capacity of the reservoir 3,000,000 gallons. The dam had been under repair. Much damage was done and one life was lost.

The bursting of a dam of a reservoir at the head of Goodrich Creek, 12 miles from Baker City, Ore., on June 15, 1896, caused extensive damage in the valley below. One farm house was carried away and an entire family of seven persons were drowned.

The bursting of a dam of the lake at the fair grounds at Staunton, Va., Sept. 30, 1896, due to high water, caused a flood which did considerable damage to property and in which five lives were lost. (Eng. Rec., Oct. 10, 1896.)

A small dam near Ward, Jefferson County, Col., burst July 9, 1897. Two lives were lost and $50,000 worth of property was destroyed.

Two of the reservoir dams on Beaver Brook, near Ansonia, Conn., were carried away on March 26, 1884, liberating about 50,000,000 gallons of water. One railroad and two highway bridges were destroyed, and the total damage amounted to about $250,000.

A rock-filled dam across Pecos River, six miles above Eddy, New Mexico, failed on August 6, 1893. It was 1,040 feet long, 45 feet high, 21½ feet wide at water level and 6½ feet at top. On the upstream slope the rock was laid 1½ to 1, faced with earth with a slope of 2 to 1, and the downstream slope was 1 to 1. (Eng. Rec., Aug. 26, 1893.)

On September 18, 1890, a dam near the head of Broad Brook in the town of Ellington, Conn., gave way, and the flood swept down the valley, carrying away five dams, two railway trestles, six highway bridges and other property, making an aggregate loss of about $50,000.

A masonry dam on the Colorado River at Austin, Tex., costing $1,400,000, failed on April 7, 1900. It was 1,275 feet long, 68 feet high, and 66 feet thick at the base. A freshet and great depth of water flowing over the crest forced 500 feet of the dam down the river. The damage to property amounted to about $500,000. (Eng. Rec., April 14 and 21, May 19, June 30 and July 28, 1900.)

In addition to the cases cited above, forty-eight other failures of dams and reservoirs in this country have come to my notice. It is very unfortunate that the records relating to them do not contain any description of the structures, the purpose of their construction or the cause of the failures.

Rapid Base Line Measurement for the Ninety-Eighth Meridian Triangulation.

Some very important changes in the manner of measuring primary base lines have been instituted in the Coast and Geodetic Survey, which will doubtless receive the hearty approval of all who are acquainted with the possibilities and limitations of that branch of surveying. Early in 1899, Dr. H. S. Pritchett, then Superintendent of the Coast and Geodetic Survey, made several suggestions preliminary to the work of triangulation along the ninety-eighth meridian. Among them were the following: First, that it would be better to measure many bases at comparatively short intervals with a moderate degree of accuracy, than to measure few at longer intervals with a very high degree of accuracy; second, that the bases could be measured at a much smaller cost if one party measured as many as possible in one season in advance of the traingulation than if

Location of Bases.

the customary plan were followed of measuring one base at a time; third, that the degree of accuracy which it would be necessary or desirable to attain should be ascertained, and the plans for the measurement made with reference to securing an accuracy no greater than this as quickly and economically as possible.

In a report "On the Measurement of Nine Bases Along the Ninety-eighth Meridian," Appendix 3 of the 1901 report of the Superintendent of the Coast and Geodetic Survey, is given a detailed and elaborately illustrated description by Mr. A. L. Baldwin, computer and chief of party, of the methods used in following out these suggestions, and also a preface by Mr. John F. Hayford, inspector of geodetic work, stating in more detail the reasons for conducting the work in the manner stated. A resume of this valuable report follows.

An examination of the manner in which errors of length in a triangulation accumulate in passing from a base to a remote side, shows clearly that the most accurate portion of the operation is the base measurement; that the accumulation of error is most rapid in passing from the base to the border lines of the base net; and that the errors of length accumulate much more slowly in the chain of triangles between the base nets than in the base nets, but that even here the errors are large in comparison with those involved in the base measures. Accordingly the reconnaissance party sent out to select the sites for the bases was instructed to pay especial attention to securing good geometrical conditions in the base nets even at a sacrifice of accuracy in the bases, and was informed that the accuracy of the base measures could be kept up to the standard on any grade not exceeding 5 per cent., and that narrow, deep ravines should not be considered as obstructions.

It became evident from a consideration of previous triangulation in the United States and in foreign countries that very little increase in the average accuracy of the lengths of the triangle sides would result from increasing the accuracy of the base measurement beyond that represented by a probable error of 1 part in 500,000. The party was therefore instructed to keep as far within this limit as possible by the use of good judgment and skill, but to restrict the time and money expended upon each operation to that required to keep barely within this limit.

A careful study of past base measures indicated clearly that although they are ordinarily of more than sufficient accuracy in so far as accidental errors are concerned, they have two weak points with reference to constant errors. Each base has usually been measured with but one set of apparatus, or at least with but one type of apparatus; and the apparatus has usually been standardized under one set of conditions at headquarters and used under another set of conditions in the field. Almost without exception, whenever a base has been measured with two types of apparatus, discrepancies between the measures have developed which were too large to be consistent with the degree of accuracy which was supposed to be attainable with the apparatus. In the base measures of 1900, it was therefore decided to reduce such errors to smaller proportions by making the length of each base depend on several sets of apparatus of two different types, and it was also determined to standardize the apparatus in the field under conditions as nearly as possible corresponding to those encountered in the base measures.

The nine bases measured in this work, together with the Salina base of the transcontinental triangulation along the thirty-ninth parallel, control the lengths on 1,100 miles of the arc of the ninety-eighth meridian. Their location and the route followed by the party in going from one to another is shown on the accompanying map. The date of arrival and organization of the party at Shelton, Neb., was June 16, 1900, and after this date 26 days were occupied in transportation from each site to the next. The departure from Seguin base began on January 18, 1901. In a period of six months, therefore, all the apparatus was standardized twice under actual working conditions, and these nine bases, averaging 7.7 kilometers (4.8 miles) in length, were measured with an average probable error of 1 part in 1,200,000, this accuracy being obtained largely through skill in manipulation. The largest probable error in the measurements was that at the Alice base, 1 part in 690,000; and the smallest was at the Bowie base, 1 part in 1,639,000.

The Eimbeck duplex base bars, two 100-meter tapes, and two 50-meter tapes were used in the measurement. A portion of each base about one kilometer (3,280 feet) in length was measured with all five sets of apparatus, and, of the remainder of each base, about one-fifth was measured with the duplex bars and about two-fifths each with the 50-meter and the 100-meter tapes.

All the apparatus was standardized at Shelton before beginning operations, and at Seguin afterwards. As the comparators were located only a short distance away from their respective base lines, the lengths of each of the five sets of apparatus were determined under the same conditions in which they were used, and by the same observers. The comparators consisted of two spherical-headed brass bolts cemented into stone monuments imbedded in the earth approximately 100 meters apart. As the comparator interval was to be determined by means of the iced-bar apparatus, preparations were made accordingly. Well seasoned pine posts, 5½ inches square and about 6 feet long were driven to about half their length every 5 meters apart between the monuments to be used as supports for the intermediate microscopes. The end microscopes were provided with more stable supports. Alongside of the post three sections of portable track were moved along with the progress of the measurement and were supported on intermediate stakes. On this track the measuring bar was supported.

The comparator interval was determined by means of a 5-meter steel bar immersed in melting ice. The length of this bar referred to the international meter at Paris, is known with a probable error of 1 part in 4,500,000. The bar was properly set to grade by means of a striding level resting on plugs about a meter apart, and its alignment was accomplished by mounting a theodolite in the line of the end microscopes and bringing the intermediate microscopes into position as each was adjusted. What is known as a cut-off cylinder was used at the ends to refer the line to the brass bolts. The speed of this measurement varied only slightly from 100 meters per hour, although single measures of the comparator interval were recorded in 50 minutes.

The distance between the terminals of the Shelton comparator was measured ten times with this iced-bar apparatus and the Seguin comparator five times. In the course of these measurements it was seen that there was a decided tendency toward a large result when measuring away from the sun. This was accounted for by the fact that each microscope was shaded only while the corresponding measurement was being made. As soon as the microscope is shaded, the side of the iron cap toward the sun begins to cool, and the microscope therefore begins to move toward the sun. As a result of this, when the measurement proceeds toward the sun, too short a length for the interval is obtained, and when proceeding away from the sun the value is too large. This discrepancy is of course small, and by making two measurements, one directly after the other and in the opposite direction, and taking the average as one determination of the length, this source of error was eliminated. Taking into consideration the probable error in the length of the iced-bar itself, the probable error of each 100 meters of the bases measured, so far as the determination of the lengths of the comparators is concerned, is 0.037 millimeter, or 1 part in 2,700,000. This was a much higher degree of accuracy than was required.

Each unit of the duplex bar apparatus consists essentially of two 5-meter measuring bars of steel and brass respectively, freely supported side by side in a brass case. The measuring bars are of exactly the same length only at a certain temperature known as the duplex temperature, and the difference between the mean temperature of the bars during a measurement and this duplex temperature is in proportion to the difference between the values for the length recorded by the steel and the brass, respectively. There is thus provided a means of obtaining from the coefficients of expansion of the two metals the mean temperature of the bars throughout the base line measurement, from which what is known as the duplex measurement can be obtained. In addition to this, three thermometers are placed with their bulbs between the two bars, and a record is kept of the indicated temperatures throughout the measurement. By using the measures obtained from the two bars as entirely independent values, and these observed temperatures as the actual ones, two additional values for the length of the line are obtained. Thus by the use of the duplex bars three partially independent determinations of the length of the base are made simultaneously, and are known as the duplex, the brass, and the steel, respectively.

The method of manipulating this duplex bar apparatus was modified somewhat from that of previous surveys in order to gain speed. No attempt whatever was made to protect the apparatus from the weather. On starting a measurement, the trestles having been arranged at a convenient height, but in the rear of the section mark, the zero bar was aligned and put in position face up, the front end of that component which was in the exact line of the base being brought over the section mark. In referring to the section mark a transit was used at a distance of 30 feet and at right angles to the bars. The other component was then set normal, either by the plane mirror or with the front scale whose reading when normal was known. The components are said to be set normal when their front agates are in the same plane normal to the bars. The bar scales on this bar were then read, recorded and checked. The temperature was noted, and if higher or lower than the duplex temperature (26.45 degrees Centigrade) the brass component was shifted backward or forward by an amount sufficient to permit the measuring of 250 meters if possible without another set-back or set-up. This was done to make as few delays as possible in the measurement.

The first bar of the measure was then placed on the trestles and simultaneously with the rough alignment by the observer at the forward end, the rear end of the bar was raised or lowered by means of a sliding wedge, and securely clamped when at the correct height. The preliminary contact was then established by seizing the bar under the left arm and sliding it backward bodily while the contact slides were held back and protected as much as possible with the forefinger of the left hand. The signal "Ready for line" was given when this approximate contact was begun, and generally with its completion the perfect alignment was completed by the forward observer, who bisected the line flag at the next section post ahead, which had previously been set five-heights of an inch from the line. It will thus be seen that one of the components traveled in the exact line of the base. The final contacts were then established between the components as quickly as possible by means of the contact screws, and at the same time the thermometers and the inclination sectors were read and recorded. This completed the laying of the first bar. Unless a set-up or set-back of brass became necessary no more scale readings were taken until the end of the half section, usually after the laying of the hundredth bar.

Next the zero bar was launched and carried ahead by two men and brought into line and contact as the second bar of the measure. The inclination sectors and the thermometers were then read, checked and recorded as before. On the third bar and until the ninth was reached the thermometer readings were omitted, the mean temperature from eight sets not differing materially from that from twenty. At the end of the half section, where a stop was usually made, the forward agate of the steel component was referred to the ground and the scales of the last bar read and checked. The brass component was then shifted to normal with steel, the scales read and the bars left standing. On resuming the measure the front agate was referred to the ground mark and the start made as described for the beginning of the section. When transferring to the ground the readings were never made on a scale, but the end of the measurement was preserved by a mark on a copper tack so that the set-ups (or set-backs) could be checked at any time with a quarter-meter scale and dividers.

DUPLEX BASE BARS IN USE.

The observer in charge of the trestles spaced them and made them stable. The gain in speed over former measures was in a great measure due to the observer aligning the trestles simultaneously with the rough bar alignment, so that when he finally left the bar it was certain that the trestles ahead were in line. He then went to the front trestle, and by sighting under the fixed bar set its roller at the general grade of the ground. This enabled the forward bar man to immediately clamp his forward trestle and assist in the work at the rear trestle. At the conclusion of the measurement of 250 meters and at 750 meters the bars were both reversed with care, but no scale readings were made unless a shift of the brass was required to equalize the amount of projection of the components beyond the protecting case. The speed with which these duplex measurements were made varied from a little over 25 bars per hour at the start to 100 bars per hour for a half section at the Seguin base. The average was 52.9 bars (about 870 feet) per hour.

An inspection of the results obtained from the duplex apparatus reveals the fact that the result from steel is in every case between that from duplex and that from brass. Moreover, the differences, steel minus duplex and brass minus steel, bear a fixed relation to each other. The mean value of this ratio is 1.67 and the individual values agree closely with this; so that there is not a single case where a correction of less than 0.2 millimeter to one of the values will not produce exactly the ratio 1.67. This peculiarity forms a valuable check on the computation. An inspection of the results obtained from this apparatus at the Salt Lake base in 1896, in which measurement the bars were carefully protected from inequalities of weather, reveals this same ratio. That this peculiarity is due in some manner to inaccuracies in temperature measurement is shown by the fact that wherever the range in temperature was least the results from the three methods are most nearly in accord, and in special cases where the temperature was constant the accord is perfect. Computing the probable errors of the three values obtainted and assigning weights in inverse proportion to the squares of the probable errors, the weights of the three determinations were: duplex, 10; steel, 5; and brass 2.

A careful consideration of the probable errors obtained in measuring the comparator intervals, compared with what would be expected in a 100-meter length judging from the probable errors obtained in measuring the nine test kilometers, led to the conclusion that the results from the duplex follow closely the laws of accidental errors, the probable errors increasing but little faster than the square root of the lengths. With the steel and brass it is quite different. In the case of the steel the errors increase very closely as the length, while with the brass the errors increase more rapidly than the length. Because of the removal of the tent and the subjection of the bars to different conditions of the weather, the probable errors have not been much affected for the duplex result, but the probable errors for the steel and brass have increased greatly. The evidence of constant errors is therefore greatest in the results from brass and steel, while the duplex result is apparently not entirely free from such errors.

Both the 100 and the 50-meter tapes used in the base measurements were about ¼ inch wide and 1/50 inch thick, and weighed about 22 grams per meter. Instead of graduations ruled on the tape itself there are end graduations ruled on silver sleeves riveted to the tape.

Only one tape stretcher was used, the rear end of the tape being simply held by a staff driven into the ground. The spring-balance used to apply the proper tension to the tape was one reading directly to 25 grams. The tension used was 15 kilograms (33 pounds), in place of 11.5 kilograms formerly used. The two thermometers used were tied in a horizontal position near the ends of the tape, with their metal backs in contact with it.

When in use the tapes were supported at 25-meter intervals, the intermediate supports consisting of wire nails driven into 2x4-inch stakes. These support nails were ranged into line for any tape length by means of one telescope of the binoculars brought to the right height at the forward end of the tape. At the forward end the tape was supported and aligned over the marking stake by the tape stretcher. These marking stakes were 4x4-inch posts securely driven to the proper height, and with the top surface about parallel with the surface of the ground. Copper strips were nailed on top of these posts parallel to the line of the base and distant from it half the width of the marking sleeve of the tape. The thickness of these strips brought their top surfaces into the plane of the marking sleeve and allowed the tape graduation to be prolonged onto this strip by means of a sharp awl and without the use of a try-square.

MEASURING COMPARATOR WITH ICED-BAR APPARATUS.

The tape measurements were all made at night Eight men for the 50-meter tapes and twelve for the 100-meter tapes were employed in the measurement when possible. However, it is stated that it was seldom possible to use this number without delay to the leveling, and eight men were often used when measuring with the 100-meter tapes and only six with the 50-meter tapes. For the 50-meter tapes there were required two observers, one at each end, who also read the thermometers, and the front observer also helped to carry the tape ahead; one recorder, who also furnished the light for reading the tension; two men to apply the tension at the front end and hold it in the rear; and three men to handle lamps and carry the tape ahead. The field procedure was as follows: When the balance had been brought to the proper height and nearly to the proper reading the observer at the front end called "Tension." As soon as the rear-end observer had adjusted the tape graduation to coincidence with the mark on the copper strip he called "Contact." The tension was then made perfect and when the position of the front graduation had been marked the front observer called "All done," and both observers read the thermometers. The front observer unhooked the tape from the balance, and at the command "Come ahead" each carried the tape above his head to the next stake.

The mean speed attained in this process was two kilometers (6,560 feet) per hour, and a single kilometer was measured in 15 minutes. As far as the actual measurement is concerned the speed with the 100-meter tapes was somewhat greater than that with the 50-meter tapes. The former varied from 1.31 to 2.86 kilometers per hour, and the latter from 1.15 to 2.27 kilometers per hour. The speed of all the measurements increased in a very marked degree as the men became familiar with their various duties. The determination of the lengths of the tapes by the 100-meter comparators was carried on in the same way as any similar section of a base was measured except that with the end microscopes pointings were made on the end graduations of the tape after making the readings on the cut-off.

The rather unusual topography for a base line encountered on four of the nine lines deserves notice. No grading on any of the lines was attempted, and the 25-meter spans of the tape measurement were nearly parallel to the surface of the ground traversed, except where such parallelism would necessitate placing an intermediate support below the grade of the marking stakes, a tall support being substituted in all such cases. On section 1 of the Lampasas base it was necessary to break the grade (have the middle support above the grade of the marking tables) on three-fifths of the section. On this section also the maximum grade of the season was encountered, 3.15 meters in 25 meters, or 12.6 per cent., which involved a correction to the measured length of 201 millimeters. No appreciable loss in accuracy was found to result from the measurements on these grades.

The results of these base measures showed that the use of 25-meter intervals instead of the 10-meter intervals formerly used was fully warranted. As a matter of economy this change shows a reduction in labor of preparation of something over one-half, by reducing the number of tape supports in a kilometer from 100 to 40. If the reduction in the lumber and the cost of transporting it were added, the comparison would become still more favorable to the long interval. The setting of the supports was done by a party of four or five persons, consisting of one officer who had immediate charge of the work and handled the forward end of the tape, one officer who aligned the tape supports, and two or three men. The time necessary for such a party to set one kilometer of tape supports varied from two to six hours.

In comparing the work done with the tapes with that done with the duplex bars, it is found that 7.1 days' work for one man was required to measure a kilometer twice with the tapes, and 19.5 days' work with the duplex apparatus. In making this comparison one-half of all the time required for the leveling was charged to the tape measures, and none to the duplex measures, because the profile of the line necessary when bar measures only were made would require much less time than the leveling for the grade of the tape. From this it is seen that the labor required for the bar measurement is 2¾ times that required for the tapes. It is probable, however, that the accuracy is greater from the duplex for two reasons: First, the duplex gives three results which, although they are not independent, are desirable checks on a portion of the accidental errors to which the apparatus is subject; and second, because the errors due to determinations of the grade are displayed in the case of the bar apparatus, while in the case of the tape measures such errors would affect both measures alike.

The probable error of a single measure of a kilometer when computed from all the sections was slightly less for the 50-meter tapes than for the 100-meter tapes; and the ease with which the 50-meter tapes may be adapted to obstructions of topography makes the labor of setting the supports about equal to that required for the 100-meter tapes. The choice between the two then must be made in the comparison of the number of operatives required with each length of tape. The minimum number for the 100-meter tape is eight, and for the 50-meter tape is six, which means that it always takes one-third more help to manipulate the longer tape.

While the speed of measurement with the 100-meter tape is about one-fifth faster than with the 50-meter tape, this is unimportant because the time required for the measurement is much less than that required for the preparation of the line for measurement, and because it is always desirable to keep the measurement following closely the setting of the stakes. In measurements through pasture it was found convenient to complete the measurement as soon as three kilometers had been prepared. The work of measuring three kilometers was readily accomplished in an evening without regard to whether it was the 100-meter or the 50-meter tape. The conclusion therefore is that the 100-meter tape has few if any advantages over the 50-meter tape, and requires a party at least one-third larger for its manipulation.

Constant errors peculiar to each apparatus were revealed in these measures, and it may be inferred that the absolute accuracy is at least as great as in previous bases where but one type of apparatus is involved. These constant errors are shown in the results of the measures of the nine test kilometers. The maximum range in the results was 20 millimeters (nearly an inch), the tapes as would be expected, agreeing among themselves more often than with the bars. The bars give a smaller result than the mean, ranging in the kilometer from 2.1 to 10.3 millimeters. One of the 100-meter tapes shows a tendency to give the largest result, being above the mean in seven of the nine cases. The source of these constant errors is still problematic.

The total amount expended for field expenses in these operations was $7,511.65. This includes all items of transportation, freight, etc., beginning and ending in Washington, all material, camp equipage, and pay and subsistence of the entire party, except salaries of officers. After adding the pay of the officers and the cost of preparing the results for printing, including all computations, the total cost of the bases is $11,074.78, which is about $1,231 per base, or $260 per mile.

A Liquid Air Plant that was erected some time ago at Cornell University has been tested by Messrs. Frank Allen and William Ambler, and the results are given in the "Physical Review." The compressor is of the four-stage type, and the air is cooled as it leaves each cylinder, passing finally into the liquefier, where a pressure of 180 atmospheres is maintained. A 30-horse-power motor supplies power. Liquid air begins to flow from the nozzle of the liquefier within 10 minutes of the start. The quantity of air liquefied is about 5 per cent. of the amount passing through the system. The performance of the plant is 0.28 pound per horse-power-hour; the efficiency of compressor and liquefier, 2.2 per cent.

An Unusual Water Supply Plant.

The town of Arad, in Hungary, derives its supply of water from a gravel stratum underlying an impervious bed of clay. The wells are driven to a depth of about 135 feet and the water is raised by means of an air lift. It is then filtered by means of the Fischer system of plate filters, descriptions of which have appeared from time to time in The Engineering Record, passes into a storage reservoir and is then pumped into the town mains by two triple expansion Worthington pumps. Before final distribution the water passes through a large air chamber to equalize the pressure in the various mains. The following description of this plant, which combines so many interesting and unusual features, has been taken mainly from an account of the works published in "Engineering" some time ago.

The wells, of which there are two, 9 inches in diameter, are about 135 feet in depth, and pass through a layer of clay 20 feet thick, the bottom of which is about 63 feet below the surface. Below that point the material passed through is mostly gravel and sand, with a few thin streaks of clay. Each well is capable of delivering 540 imperial gallons per minute, and only one is ordinarily in operation at a time, as that is found to deliver sufficient water for the needs of the town. The supply of compressed air for raising the water is carried down the well by means of a wrought iron tube. The air issuing from the bottom of this tube through a suitably arranged connection, raises the water through the casing of the well into a small cast iron well at the surface. The compressor furnishing air for the lifts has compound steam-jacketed cylinders, two in number, each being 11 inches in diameter, the stroke of all the cylinders being 18 inches. The exhaust steam from the engine is carried to a surface condenser fixed below the floor of the engine house, the circulating water required for the condenser being supplied by connecting thereto the pipe which conveys the water from the cast iron service well to the filters.

The Fischer filter plates were first devised at the city of Worms because the capacity of the sand filtration plant there had been reached and no further extensions could well be made along the old lines. The engineers in charge of the works, noting that the actual work of purification was effected by the top layer of sand, 3 or 4 inches thick, set to work to devise a means of supporting this filtering film in a manner more economical of space than by means of a horizontal bed of sand. Their studies resulted in the production of a hollow artificial stone block about 39 inches square and 8 inches thick, the interior space being about 0.8 foot wide.

These blocks or plates are made of quartz sand carefully washed to free it from clay or earthy matter and then mixed with powdered glass. This mixture is placed in suitable molds and burnt at a temperature of from 1,800 to 2,100 degrees Fahrenheit. By this means the glass is melted and binds the grains of sand together without filling the interstices to an appreciable amount.

In the filter chambers the plates are placed vertically in the water, thus giving a considerable filtering surface, though occupying a small area, and the plates being hollow, the filtered water, which accumulates in the interior, is removed by means of pipes to the filtered water reservoir. The operation of cleaning is effected in the simplest manner in the case of the Fischer plate filters, by reversing the direction of the flow, thus allowing the filtered water to percolate through the plates from the inside to the outside, which is said to clean the surface of the plate in about ten minutes. An installation on the Fischer system, it is stated, only occupies one-eighth of the space required for a sand filter of equal filtering capacity.

In the works at Arad there are four filter chambers with concrete walls and floors, each 27 feet long by 10 feet 2 inches and 12 feet 2 inches deep. They are covered over with brick and concrete arches similar to those used for the filtered water reservoir. Each of the chambers contains 100 filter plates placed on edge in two tiers, each two plates being connected at the top to the horizontal collecting pipes running lengthwise of the chambers. In the inlet chamber an overflow pipe is arranged so that the level of the unfiltered water will not exceed a fixed height. The collecting pipes for the filtered water are connected in a central valve chamber to the force main for the purpose of cleaning the filters. At the other end of the valve chamber are the two outlets into the filtered water reservoir, which is divided into two sections with a total storage capacity of 66,000 imperial gallons.

From the reservoir the water passes through a 12-inch pipe into the pump well sunk in the basement of the engine house, the pumping engine and the air compressors for the air lift being housed in the same room. The water is pumped from the well into the town mains, by means of two triple-expansion Worthington pumps, each having six steam-jacketed steam cylinders in three pairs of 6, 9 and 16 inches diameter respectively. The pumps are provided with surface condenser and two double-acting water plungers of 10 inches diameter, all having a uniform stroke of 15 inches. Each pump is capable of delivering 666 imperial gallons of water per minute against a head of 125 feet. From the main pipes the water raised is carried into and through a large air vessel of wrought iron 20 feet high by 5 feet in diameter, for the purpose of equalizing the pressure on the town mains; and, as an additional security, a safety valve is attached to each of the town mains (in duplicate) leading from the air vessel. For the purpose of supplying steam for the steam-engine, the air compressors, and the various pumps, two marine type boilers are provided.

In connection with the compressed air lift an arrangement for intermittent working is used which suits cases like that at Arad, where the supply of water flowing to the well is not sufficient for constant working. Messrs. Hughes & Lancaster, of London, were the engineers and contractors for these works.

The Number of U. S. Patents issued during 1901 was 27,292 and the number that expired was 19,147. More patents were issued to residents of Connecticut than any other State, in proportion to population, and then followed the District of Columbia, Massachusetts, New Jersey, Rhode Island, and Colorado. Of patents granted to foreigners, Germans received the largest number.

An Unsuspected Leak in a large water main was detected in St. John, N. B., last year under circumstances which show clearly how large a waste of water may occur and yet be unnoticeable at the place where it takes place. In this instance the water came to the surface 400 feet from the cracked pipe from which it escaped, and many pits had to be dug before the spot was located, as the water flowed in a blind drain near the pipe. In mentioning the matter, Mr. William Murdock, the city engineer, states that a sheet of rubber packing was placed over the crack, which was 2½ feet long, and covered by an iron plate, the whole firmly held by nine heavy iron straps.

The Power Plant of the Stecher Lithographic Company, Rochester, N. Y.

The Stecher Lithographic Company has recently completed a model plant in Rochester, N. Y., facing the grounds of the University of Rochester and located in a quarter of the city that has led the company to pay considerable attention to the appearance of both works and grounds. The plant is all under the one roof and consists of a 146x225-foot two-story mill construction building with saw-tooth roof, a headhouse containing the offices which rise above the saw-tooth portion with a flat roof, and an extension containing the power plant. Toward improving its outward condition, the grounds, which are large enough to allow for future buildings, have been graded and planted with grass, and instead of a more or less lofty smoke stack, forced draft is provided for the boilers with a short steel chimney extending but a few feet above the power-house roof. The plant is equipped for the electric transmission of power and is warmed by the blower system.

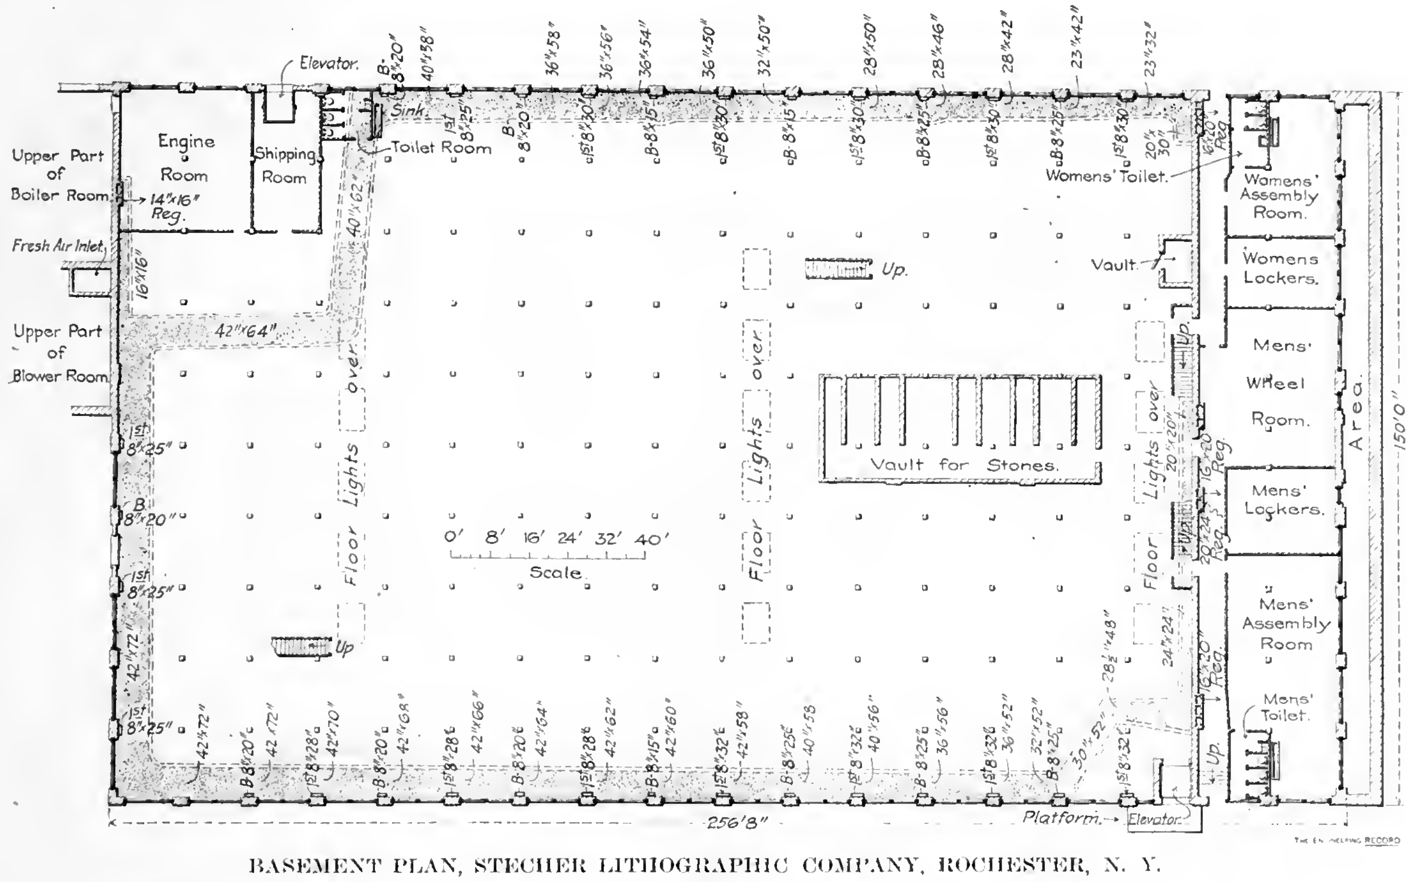
A plan of the basement of the plant in the accompanying drawings shows the outline of the buildings. The general basement floor is a few feet above grade level, while the headhouse basement, which is given up to the men and women employees, as indicated, is below grade. The two floors above in this part of the works are occupied chiefly by the offices of the company. The saw-tooth roof is in five sections, each about 29 feet wide and 225 feet long, with the skylights facing in the regular way toward the north. There is a large amount of window surface in the side walls, but to allow as much light as possible to the basement, floor lights are provided in the first floor. The buildings are equipped throughout with an automatic sprinkler system furnished by the General Fire Extinguisher Company, of Providence, this system connected on the city mains and arranged to receive water also from a fire pump installed in the extension. Two Otis freight elevators electrically operated have been installed, one serving the floors of both the main building and the office structure.

A plan of the powerhouse is also shown herewith. It consists of two rooms, one for the boilers and auxiliary apparatus and the other principally for the heating apparatus, the electric generating machinery and the switchboard being located in the adjacent corner of the main floor of the factory. The boiler room contains two 200-horse-power water-tube boilers built by the National Water-Tube Boiler Company, of New Brunswick, N. J., and there is space for an additional boiler of the same capacity. Each boiler is equipped with the Jones underfeed stoker, furnished by the Underfeed Stoker Company of America, and is operated under forced draft for which a Sturtevant blower belt driven from a Sturtevant 9.78 horse-power vertical engine has been installed.

The coal for the plant is stored in a pit extending underground from the end of the boiler-room. It is located immediately underneath a railroad siding to the works and coal is dumped from the cars through three covered coal holes. It is built with brick walls and has an I-beam and brick arch roof supported underneath the rails of the siding by cast-iron columns. It is about 6 feet high and has a capacity of about 80 tons. There are three openings from it into the boiler room, corresponding to the three boilers. The forced draft fan is of the double-inlet type, with a 42-inch blast wheel and is designed to supply the ultimate installation of three boilers. Under present conditions it is run at 668 revolutions per minute. The smoke stack is of steel, 5 feet in diameter and at the top is 50 feet above the boiler room floor.

At present but one of the two generating sets that it is intended to install is in place. This consists of a horizontal tandem-compound McIntosh & Seymour engine, 13 and 19x15 inches in cylinder dimensions and a General Electric multipolar direct-current generator directly connected to it, rated at 435 amperes at 230 volts and 250 revolutions per minute. Steam is generated at 100 pounds pressure and extra heavy piping with peaned flange joints has been provided. Each boiler has a 5-inch connection to a header which is 10 inches in diameter. Its area is thus four times that of each boiler branch and it is capped with two blank flanges, one in the boiler room for the third boiler and the other in the engine room for the second generating set.

The boiler-feed pumps are located in the boiler room between the boilers and the main building wall, the fire pump is located in the fan room, as stated, and all these, together with the forced draft fan engine and a 29.6 horse-power horizontal engine for driving the heating system blower receive steam from the main header. The exhaust from this machinery and from the electric generating set is collected into a 10-inch main near the feed pumps, with the exception of that from the fire pump, which was most conveniently given an independent free exit to the atmosphere. A grease separator of the Austin type has been inserted in the pipe for the general exhaust, after which the exhaust steam is utilized for heating purposes. It first passes through a vertical Berryman feed-water heater, and may then pass into the heating plant for the building or into the atmosphere through a 10-inch exhaust pipe, this fitted in the usual way with back-pressure valve to allow an escape of steam only when its supply is greater than its demand. This has an exhaust head on top to catch condensation.



BASEMENT PLAN, STECHER LITHOGRAPHIC COMPANY, ROCHESTER, N. Y.

The condensation from the heating system, and the drips from the live-steam lines, from the feed-water heater and from the exhaust head are all conducted into an iron receiving tank behind the boilers, 3 feet in diameter and 6 feet long. To this is also brought, when necessary, fresh water from the city mains and the boiler feed pumps draw from it, pumping through the feed-water heater to the boilers. The tank is provided with a vapor pipe which joins a pipe carrying the discharge of the boiler safety valves through the roof. The feed pumps are installed in duplicate and are of the Deane duplex type, 6x4x6 inches. A Metropolitan injector has been provided as a relay to the pumps. The steam piping throughout is covered with Keasbey & Mattison asbestos sectional covering.

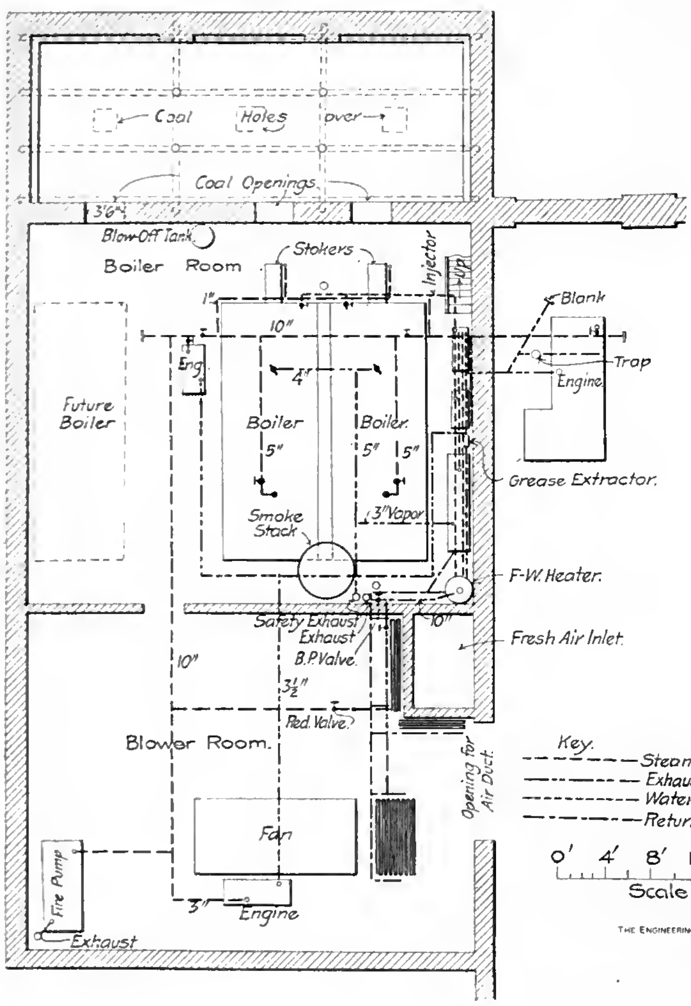
The electric installation is controlled from a black enameled slate switchboard in the engine room furnished by the General Electric Company. The board consists of two generator panels, one for the machine yet to be installed, and of two feeder panels. Two sets of bus bars are provided for light and power, and both generator and feeder switches are double throw, so that circuits can be fed from either set of busses. Each generator panel is furnished with a circuit breaker and a Thomson ammeter; the bracket type of voltmeter, fixed at one end of the board is used. Altogether 250 32-candle-power incandescent lamps and 100 800 to 1,200-candle-power arc lights are supplied. There are 80 motors all told, ranging from ½ to 10 horse-power.

The heating apparatus is of the blower type of forced circulation, as stated, with the heating medium all concentrated in the fan room. Air is ordinarily taken from the first story of the building, or it may be taken from out of doors, or partly from the building and partly from outside, the air being drawn down a shaft to a fan room. Two dampers linked together and operated by a pull chain in the fan room control the inflow of air, one damper mounted in the outside air inlet and the other in the building air inlet. At the bottom of the shaft the air passes through tempering coils, placed as indicated, and enters the fan room. It is then taken by the blower and discharged all or in part through the main heater and thence by underground ducts to flues distributed along the outside walls and delivering by vertical flues to the different outlets.

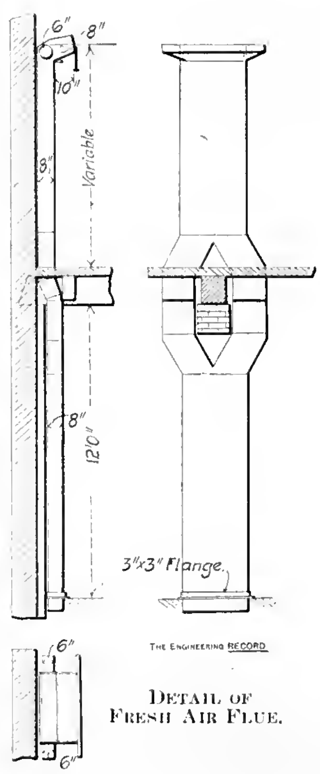
There are two groups of tempering coils, each group consisting of two sections of the usual 1-inch pipe coil with cast-iron base, one section of four pipes width and the other of two. Each section is 82 inches wide and 8 feet 8 inches high. The fan is a three-quarter housing centrifugal blower, with blast wheel 11 feet in diameter, and is direct driven from a 10x12-inch horizontal steam engine. Immediately beyond the fan is the main heater, which is provided with a by-pass underneath, the by-pass furnished with a damper controlled by a Johnson thermostat placed in the plenum chamber beyond the heater. The main heater consists of 10 four-row, cast-iron base, pipe coils of the same size as the tempering coils, the heater coils being arranged two across the width of the air passage and five deep. The steam supply to each group of five heaters is distributed from a vertical drum in the steam supply pipe, and the tempering coils are similarly supplied from one drum located near both coils and supplying two steam connections to each. In the two groups of tempering coils there are about 3,744 lineal feet of pipe and in the main heater 14,515 feet, and the whole steam heating apparatus is calculated to raise the temperature of the air supply to a maximum of 150 degrees in zero weather.

The accompanying basement plan shows in dotted line the approximate run of the underground air duct, which is constructed of brick on a concrete bottom. Assuming that the blower under operation at a speed of 150 revolutions per minute delivers 80,000 cubic feet of air, it will be found that the velocity of the air flow through the ducts, allowing for expansion of the air due to heating in the main heater, is about 2,000 feet per minute. Similarly, the velocity of the air through the vertical flues varies from 1,000 to perhaps 1,500 feet, with an average of 1,250 feet per minute. A detail drawing herewith shows the construction of the flues which are capped with three outlets in each case, two circular in cross-section and discharging in opposite directions across the adjacent windows, and the other wide and narrow and pointing toward the interior. The latter is fitted with the Shumaker distributing damper, which is a sort of bonnet hinged at the flue top and controlled by a handle pointing downward from it, to cover such a portion of the long and narrow outlet as desired. The circular openings are not provided with any gate and the office of the air issuing from them is to offset the cooling action of the windows and afford a positive air circulation from the walls toward the interior. The total area of the three outlets to each flue is equivalent to that of the flue itself, so that the average velocity of the air issuing from them is 1,250 feet per minute. In the basement the outlets are 9 feet above the floor; in the first story, from 8 to 12 feet. The flues are all 4 inches deep and are varied in size by changes of the width. As indicated, the headhouse or office building is also connected to the system, partly by flues supplied from the underground ducts and partly from overhead circular ducts in the basement, these ducts starting from the plenum chamber and having a connection with the tempered air space between blower and heater, with Johnson dampers for mixing the heated and tempered air under the control of independent thermostats. Vent outlets are provided for the office structure, the air escaping by flues to the atmosphere. The air from the works proper is taken, as stated, down the fresh-air shaft to be reheated and recirculated.

The architect for the plant was Mr. Leon Stern, of Rochester, N. Y. The general contractor for mason work was A. Friederich & Sons Company; for carpenter work Messrs. John Luther & Son; for the steam piping, Messrs. Howe & Bassett, all of Rochester.



The Power and Heating Plant.



Detail of Fresh Air Flue.

Waste Gases from the blast furnaces of the Union Steel Company will be used under the boilers of the power plant of the company's new mills. The power plant will furnish alternating current to the works, where five Westinghouse rotary converters will be installed. The electric plant includes an 800-kilowatt direct-current and two 800-kilowatt alternating-current Westinghouse generators.

The Influence of Capacity in Electric Transmission of power is well realized when its magnitude in large plants is expressed in figures. In a recent paper read before the Massachusetts Institute of Technology and printed in the "Technology Quarterly," on "Success in Long-Distance Power Transmission," Dr. F. A. C. Perrine referred to its importance in connection with the plants of the Standard Electric Company, and of the Bay Counties Power Company, in California, where transmission of approximately 150 miles is undertaken at 50,000 volts and 60 cycles per second. In these cases the charging current is approximately 40 amperes, or, in other words, the line requires the full capacity of a 2,000-kilowatt machine for charging it as a condenser. The complete neutralization of this capacity effect, he finds, would require the continuous working of something in excess of 5,000 kilowatts of induction motors with average normal power factors. The power house is practically unable to have much knowledge of the loads actually applied on the lines, except by observing the wattmeters or the wheel nozzles, as the current from no load to a load of several thousand kilowatts remains practically constant. As there are many branching lines supplied from the system, the dynamos are operated with constant electromotive force and the regulation of the long lines is affected by the capacity, which influences everything from the step-up transformers to the last motor. To overcome troubles due to this source, the Bay Counties Power Company has arranged to place upon its lines impedance coils capable of practically neutralizing the entire capacity of its long lines. With the capacity of the line neutralized, Dr. Perrine advocates keeping the load as nearly non-inductive as possible by continuous care in the balance of synchronous against induction motors.

Complicated Underpinning.

The new steel building for the Bank of the State of New York occupies a lot about 100 feet square on Exchange Place, between William and Broad Streets, New York, and will rise to a height of about 240 feet above the curb. Unlike some of the very tall office buildings in the same district, its lower stories do not extend to a great depth below the curb, and the cellar floor will be only about 21 feet below grade, but the foundations have been carried to a much greater depth and the work on them has involved some difficult and delicate operations in underpinning the adjacent walls of the neighboring high buildings. The soil and general conditions here are similar to those where other tall steel buildings have been erected in this vicinity, as the Corn Exchange Bank, the Blair Building, the Stock Exchange, the Hanover Bank and others which have been recently illustrated in the Engineering Record, but some restrictions were involved which made it necessary to introduce special features in the auxiliary work which will be here described.

The soil consists of earth and fine sand with a little gravel to a depth of about 30 feet, then about 6 feet of clay in thin layers, then 4 feet of hard pan and then rock. Mean high tide level is about 15 feet below the curb and the ground water level corresponds approximately with it. Below that plane the saturated soil becomes quicksand which is slippery with mica and sticky in places with clay. All the foundations are concrete piers sunk in pneumatic caissons to rock, and those adjacent to the lot lines have rectangular cross-sections about 7 feet wide and 14 feet long with only 2 or 3 inches clearance between their long sides and the walls of the next buildings, which were of ordinary brickwork with concrete footings in the sand about 8 feet below the curb. There was no cellar under the old building which formerly occupied the site of the bank building and the 3-foot excavation there was increased to 6 or 7 feet after the old buildings were razed. Then the caissons were sunk, and after the completion of the foundation piers inside them the cellar excavation will be carried to a depth of 21½ feet in the center and to 18 feet around the edges of the lot.

The foundation piers along the lot lines are set with only a few feet clearance between their ends so that they form a retaining wall with short gaps and will serve to prevent much caving in of the sides, when the cellar excavation is made below the footings of the old walls. The sinking of the caissons, however, in such loose soil was considered sure to produce some settlement, which was estimated at 2 inches at the lot lines, and would be likely to cause some flow of material from under the shallow footings, both results being inadmissible for the integrity of the tall buildings. It was, therefore, determined to support them so that they could be continually raised to compensate for any settlement while the caissons were being sunk, and to permanently underpin them afterwards with new footings carried down approximately to the level of the new cellar floor. This plan was complicated by the necessity of leaving a large space in front of the walls and next to them, clear for the sinking of the caissons. It became necessary to devise special temporary supports for the wall and to change its bearing four times while different supports were successively introduced and withdrawn.

The office building on the east side of the bank, at No. 44 Exchange Place, has a 6-story wall about 20 inches thick at the base, 35 feet long and 90 feet high above the street which was estimated to weigh about 12 tons per lineal foot. The face of the wall was braced by two sets of 12x12-inch inclined shores, A and B, set on jackscrews, and a 5-foot panel in the middle where the thickness was reduced to 4 inches was strengthened by special planks and braces as shown in the front elevation. The front and rear walls were weakened by vertical lines of doors and windows near the corners. The corners were supported on diagonal needle beams and the front wall was braced by three shores from the street inclined at different angles. The rear wall was cracked through vertically between windows from the foundation up to the roof, and was additionally braced by a horizontal strut to an adjacent building and by a short inclined shore in its plane, set in a lower door opening as indicated by dotted lines in the plan.

A horizontal row of holes 3 or 4 feet apart on centers were alternately cut through the lower part of the wall and through them 12x12-inch needle beams 6 feet long were inserted and supported on special 20-ton jackscrews. The jackscrews were seated on a pair of 12x12-inch longitudinal timbers, one inside and one outside the wall, which rested on two groups of long transverse needle girders about 18½ feet apart between centers of groups, and on temporary intermediate blocking which is not shown in the drawings. The needle girders were double tiers of 15-inch 60-pound I-beams 28 feet long, sixteen in one set and twelve in the other, the latter being separated into two groups, one outside and the other inside the rear walls.

Steel packing plates were placed between the two tiers so as to reduce the clear span of 14 feet of the beams in the lower tier to 10 feet for the beams in the upper tier. The groups of needle girders were located so as to lie between the wall caissons and just clear them and projected several feet beyond the inner faces of the caissons in the bank lot where they were supported on ordinary timber cribbing, also clear of the caisson locations. These are marked permanent cribs on the drawing because they remained in service until after the underpinning was completed while the other cribs, marked temporary, were removed before the caissons were set. The opposite ends

Elevation Z-Z of Preliminary Underpinning 2.

UNDERPINNING AT THE BANK OF THE STATE OF NEW YORK.

of the needle girders were carried on longitudinal sills which distributed their loads on the concrete cellar floor far enough from the face of the excavation to be considered out of danger of caving in. One needle beam was inserted in an arched opening where it was not necessary to cut through the brick wall and short blocking was put on top of it to support a horizontal longitudinal timber about 4 feet long in the plane of the wall, which had its ends nearly in contact with the intrados of the arch and formed a chord to its curve. The segmental space between the beam and the arch was packed full of thin shingles driven in tight so as to distribute the load of the beam uniformly across nearly the full span of the arch.

Several level blocks, marked L L L in the elevation, were accurately set with their lower edges in the same horizontal plane, and nailed to the face of the wall about 5 feet above the curb, for reference points. A leveling instrument was set up and their elevation taken from the permanent bench mark which had been established across the street and the jackscrews under the needle beams were operated to raise the wall ⅛ inch as determined by the instrument. Then the brickwork between the needle beams was removed sufficiently to allow a row of 5-ton jackscrews to be set on top of the lower part of the wall and temporarily support it between the needle beams, as shown in the front

UNDERPINNING AT THE BANK OF THE STATE OF NEW YORK.

elevation. These jackscrews and those under the needlebeams are indicated by full circles in the plan.

A pair of 24-inch 100-pound I-beams 30 feet long were successively introduced between the front row of jackscrews and the wall, under the needle beams and slid across on the needle girders until they were side by side under the center of the wall. The middle row of jackscrews were removed to admit these wall girders and were immediately replaced on top of them, and those under the needle beams were removed. The whole weight of the wall was thus carried by the 24-inch I-beams and the needle beams and their sills and the temporary cribs were removed and left the site clear for the caissons to be set close to the wall between the groups of needle girders. The two 24-inch I-beams were then carrying in the middle, a load of about 180 tons uniformly distributed over a clear span of 15 feet and at the street end a load of about 72 tons on the cantilever of about 6 feet clear overhang. Besides this they carried about 108 tons directly above their supports on the needle girders which did not produce flexure. Levels were frequently taken on the wall marks and the jackscrews were operated if necessary to maintain the level of the wall.

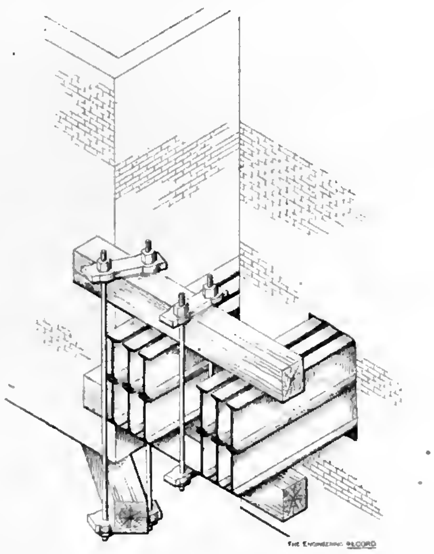
The old footing was removed and the caisson was sunk to rock with a load of about 300 tons without causing any injury or displacement to the wall or disturbing the operation of the elevator machinery and other mechanical plant installed in the building. After the caisson work was completed a trench was dug alongside and the new footing and lower part of the wall was built in it. The longitudinal sills and short needle beams were replaced and the weight of the wall was transferred to them, releasing the wall girders which were removed and allowing the lower part of the brick wall to be built on the new footing. A row of jackscrews were inserted between the top of this wall and the foot of the old wall and were screwed up to bring all the load on the new footing and release the needle beams which were then permanently removed. The weight of the building caused some settlement of the new footing and the jackscrews were operated to compensate for it and the work was allowed to remain several weeks, after which the screws were gradually taken out, one by one, and the spaces they had occupied were filled by new brickwork completing the walls. This method not only compensated for the compression of the earth under the footing, but for that which takes place in the masonry itself when fresh brickwork is heavily loaded. That the latter is not negligible when important walls are very heavily loaded is shown by the records of similar work recently executed under the same supervision and by the same contractors.

In the underpinning of the Decker Building, which was described in the Engineering Record of May 10, a section of wall 9 feet high, 20 feet long, 3 feet thick on top and 4 feet thick at the bottom was seated on a concrete base 5 feet wide and 2½ feet high which was built on the solid rock. This wall was built of selected hard brick laid up with thin joints of Portland cement mortar, and when it was seven days old the full load of 400 tons which it was estimated to carry from the upper part of the old wall and floors was concentrated on a buttress which formed an enlargement in the center of the wall. The buttress was 7 feet long and had a constant thickness of 4 feet, top and bottom.

The load was uniformly distributed on it and caused a compression of 3/16-inch, accurately measured and checked.

In the rear of No. 44 Exchange Place there is a small building with a brick wall about 12 feet high facing on the line of the bank lot. A caisson was to be sunk directly in front of it and to support it without having cribs or sills to interfere with the caisson a needle beam was put under the footing close to the side wall and the outer end of it was suspended from a 12x12-inch cantilever resting on and anchored to the needle girders under the large building. The cantilever had an overhang 3 or 4 feet long and was loaded and anchored with pairs of 2-inch steel rods with nuts bearing on 4x2-inch steel saddle plates placed transversely and diagonally across the beams and having their ends punched and spread hot so that there was no loss of metal in making the holes for the vertical rods.

The underpinning was done by the George A. Fuller Company, who are the general contractors for the Bank of the State of New York Building. Mr. A. E. Riendeau planned and executed the underpinning.



Needle Beam suspended from Cantilever on Needle Girders.

Experiments With Wet, Medium and Dry Concrete.

Some large blocks of concrete were made in January, 1901, under the direction of Mr. W. H. Parkhurst, M. Am. Soc. C. E., for the purpose of determining the effect of using different amounts of water in mixing on the character of the resulting material. The concrete was mixed by hand on a plank platform adjacent to the molds, the ingredients being measured in a box holding 4.42 cubic feet when full, and the quantities checked after measuring by weighing them. The water was also measured and weighed. The details and results of the experiment were described by Mr. Parkhurst in a paper before the Western Society of Engineers, from which the following notes have been taken; the full paper and discussion was printed in the Society's "Journal" for June, 1902.

The accompanying table gives the general data concerning the three blocks. In the case of the dry block, the endeavor was to employ enough water to make a mealy concrete but not to flush it. No amount of ramming the thin layers would bring water to the surface. With the wet concrete men could not stand on the material to ram it; the mass quaked easily, and the mortar clung to the tamping iron. In the case of the medium block, there was enough water so that the top of each layer was flushed by the tamping, but there was no quaking, and the mass was always hard. The top surface had enough free water on it to spatter when the tamping was finished. The blocks were left exposed to the sun, rain and snow for several months and then drilled and broken by plug and feather. Dragon Portland cement was used. The sand and gravel were obtained by a washing plant from the Fox River, and the crushed stone was of "medium" size.

Data of Concrete Test Blocks.

Block.	Dry.	Medium.	Wet.
Port. cement, cu. ft....	4.42	4.42	4.42
Port. cement, lbs.......	392	382	382
Sand, cu. ft...........	8.84	8.84	8.84
Sand, lbs.	908	895	908
Gravel, cu. ft..........	11.05	11.05	11.05
Gravel, lbs.	1,104	1,078	1,059
Crushed stone, cu. ft...	11.05	11.05	11.05
Crushed stone, lbs......	939	915	919
Water, cu. ft..........	1.81	2.65	3.35
Water, lbs.	113	166	209
Vol. concrete, cu. ft....	25.31	22.69	22.97
Weight per cu. ft., lbs..	136.2	151.5	151.4
Loss of weight per cu. ft. during 10 mos., lbs.	1.7	4.5	5.9

In mixing the concrete, the sand and cement were made into a mortar on which the crushed stone and gravel were spread. The materials were turned over several times by shovels and then placed in the molds, where they were tamped in layers 6 inches thick. The dry mixture was placed in its box in 25 minutes, the medium in 21 minutes and the wet in 23 minutes. The dry concrete required and received the most tamping; the wet concrete required nearly as much time to be placed in the mold because so little could be handled on the shovel. After the blocks were finished the surplus water on those of medium and wet concrete froze; this freezing was of short duration.

The blocks stood for about four months exposed to the weather before they were weighed again. As there was not enough water used in making the dry blocks to permit a finish on the sides or top, the surface could be easily abraded. The gravel and stone came away from the mass quite easily, and the block could not be handled to weigh it without crumbling the edges and top surface. At the end of the four months all the blocks were found to have lost in weight, but the loss of the dry block was not due wholly to the same causes as that of the others, owing to this abrasion. The loss at the end of ten months is given in the table. After the blocks were split, the texture of those of medium and wet concrete was excellent, while that of the dry concrete was poor and not well compacted.

The conclusions drawn by Mr. Parkhurst from his experiments are as follows: First, a medium concrete, or one that has not enough surplus water to produce quaking while having enough to permit easy and thorough ramming, is most desirable. The specification that the concrete shall not quake in the barrow nor while handling, but that it may be wet enough to quake when heavily rammed, would seem about right for regulating the amount of water to be used. Second, it is probably safer to have an excess than to permit a deficiency of water. Above all, however, it is of the utmost importance that the concrete shall be consolidated thoroughly by ramming.

In the discussion following the presentation of the paper Mr. Finley called attention to another discussion of concrete before the Society in 1896, when Mr. Alfred Noble summarized his opinion as follows: "It thus appears that while there is considerable diversity of opinion as to the exact degree of wetness concrete should have, none of the engineers quoted advise such dry mixtures as are commonly required here. The writer believes that a more homogeneous, a denser, and stronger material will be obtained if the concrete is made so wet that the mass will quake after ramming; and, furthermore, that where concrete is to be placed in contracted spaces, as between timbers, it may be with advantage made still wetter, so that it can be pushed into place with the shovel, and, by treading, filling all the spaces solidly, with no important diminution of strength at any point, but stronger as a whole." In commenting on this opinion, Mr. Parkhurst approved Mr. Noble's suggestion of using wet concrete, well rammed, in contracted spaces. If this plan is followed a very much better material is obtained, in his opinion, than where dry concrete is used, which will contain many voids.

Some experiences with concrete mentioned by Mr. Parkhurst are also of interest. In one case certain columns resting on pile foundations were constructed under the head-house of a railroad station. To protect them concrete walls were built connecting one column with the adjacent one between tracks, the walls being 4½ to 5 feet above ground and extending 2 to 3 feet below the surface. As they were built simply for protection, little attention was paid to the foundation. The ground had been solid 3 or 4 years before, but was all dug up when the building was constructed and had not been thoroughly compacted afterward. Crushed granite and limestone were used, with no sand at all in some cases, and a layer of mortar was placed over the walls as soon as possible after the molds were removed and before the concrete had set. The walls developed long, irregular, vertical cracks in many places, which were evidently due to bad foundations and not to internal stresses. They were cut to pieces in places, and the interior was in excellent condition; in all such cases where wet concrete was used the material was found to be very well compacted.

In using concrete in walls Mr. Parkhurst suggests placing the expansion joints from 20 to 30 feet apart. In one wall on the Illinois Central road there are three concrete sections, making together a length of 100 feet, with pilasters every 33 feet. An artificial joint was made adjacent to each pilaster by putting a septum in the mold and building up to it, then taking it away and building the next section, and repeating the process again. The wall was built while the temperature was 50 to 60 degrees. The temperature sometimes falls to 20 degrees below zero, and in such extreme weather the joints open fully 1/16 inch. No cracks had been observed elsewhere.

The Association of Railway Superintendents of Bridges and Buildings will hold its twelfth annual convention at the West Hotel, Minneapolis, on October 21, 22 and 23. Committee reports will be presented on auxiliary coaling stations, roof coverings for railway buildings, mail cranes, the protection of overhead structures from locomotive gases, bed plates and the use of concrete for their bases, railway pile-drivers, roundhouse pits, and materials for the wearing surface of highway bridge floors. After the convention there will be an excursion to Duluth and the Missabe Range mines.

The Many Complaints of slippery asphalt pavements in Brooklyn after light snow storms followed by mild weather have led Mr. Nelson P. Lewis to recommend paving a system of connecting streets with material giving the horses a good footing at all times. "Although petitions are constantly received for repaving with asphalt," he says, "certain streets should be set aside for repaving with granite or other non-slippery material, and while it may take some years to carry out such a plan, it should be made and adhered to in deciding on repaving for the future."

Sanitary Progress.

An address by Sir Alexander R. Binnie, M. Inst. C. E., President of the Section of Engineering and Architecture of the Manchester Sanitary Congress.

Looking back at the advances in sanitary science which I have witnessed during the past forty years of my professional life, I must congratulate the Sanitary Institute on the great success which has followed their endeavors in promoting the health and happiness of the people of this country. Compared with forty years ago, the cleanliness and sanitation of our large towns has wonderfully improved; but not only is this the case, for there has grown up in the public mind during that period a conviction that it is only by the rigid enforcement of proper sanitary regulations that the public health can be preserved. Much has been learnt and many theories have disappeared as increased experience led us to look at the subject from a practical rather than a theoretical point of view, and the main directions in which advances have been made are by endeavoring to conform to the great laws of nature which govern the removal of dead organic matter and the preservation in a state of purity of the air we breathe and the water we drink.

At an early period it was seen that it was dangerous to public health to live in the immediate neighborhood of decaying organic matter. But as to the nature and cause of this decay little was known. In a general and in a not very clear manner it was conceived that dead and decaying organic matter was in some way acted upon by the oxygen in the air, and in a certain sense burnt up or reduced to innocuous substances. During the past twenty years this crude idea has after much study by many of the ablest scientific men of our day given place to a certainty which now rests upon an irrefragable basis. It is now known that the decay of dead organic matter is a very complex process carried on by countless numbers of micro-organisms, which in their turn divide the work to be performed into various stages. In this country, where most of our sewage is water-borne, the processes are best illustrated by the functions performed by the liquefying and nitrifying organisms respectively.

At the present moment I am merely referring to the subject for the purpose of drawing attention to what I conceive to be the greatest advance in sanitary science during the past forty years. And the lesson which we learn is that advance can only be made by long and patient observations, such as those which characterize the work of such men as Pasteur, Koch and a host of others. Our object now is not to veil the process of decomposition by the introduction of what were called disinfectants and deodorizers, which too often merely resulted in substituting one unpleasant smell for another, which was more objectionable, but as far as possible to remove from our inhabited areas all decaying organic matter, and as far as possible by proper appliances, not yet completely understood, hasten those processes of nature which lead to the reduction of decaying matter from a harmful to a harmless condition.

While this may be said to be in broad general terms the lines along which we are now traveling, yet its application is rendered more difficult than might at first appear, owing to the fact that most of the sewage of our large towns is water-borne sewage, in which the quantity of decaying matter bears but a very small proportion to the total bulk of fluid to be dealt with, as well as to the fact that even the smallest quantity of decomposing matter is sufficient to destroy the purity of exceedingly large volumes of water. And from these latter facts we have gradually learnt the lesson that in a humid climate like that of Great Britain perennial irrigation on a large scale cannot be carried out with that financial advantage which was at one time expected. I do not wish by this to be understood as implying that sewage irrigation may not form a very important function in the purification of our sewage effluents, but rather that such a process is not likely to prove profitable in the long run. Besides the water-borne sewage of our towns there is always a large amount of comparatively dry matter, such as street sweepings, ash-bin refuse, and the like, which does not enter our sewers, and which is an exceedingly expensive matter to dispose of, especially in the large and congested areas of our great towns. Gradually there is growing up for the disposal of these substances a return to one of the oldest known sanitary processes, viz., destruction by fire; and under the improved modes now adopted we are arriving at processes which can be carried on with celerity and without offense, in the immediate neighborhood from which the substances are derived, and at the same time a certain amount of heat, which is evolved in their destruction can be utilized for secondary purposes.

Intimately connected with sewage disposal and the preservation of the public health is an ample and sufficient water supply, the importance of which has led almost all our large towns to resort to uncontaminated sources of supply far removed from the possibility of pollution. And there can be no doubt that a pure and uncontaminated water supply is one of the first necessaries of public health. As to whether the water should be soft or hard is largely a matter governed by local circumstances, or in some cases by trade requirements; and the experience which we have gained up to the present leads to the conclusion that provided that the water is otherwise pure and unobjectionable the public health is little or not at all affected, except perhaps in the case of such diseases as calculus and the like. I was brought up in the belief which I still hold, that a water-supply should be not only pure and uncontaminated, but beyond suspicion of any possible pollution whatever. However, in recent years I fear that a little laxity, due probably to our improved sewage purification, is creeping in, and that we find large populations supplied with water which has received directly or indirectly many sewage effluents.

From this I draw the conclusion that either our large towns, such as Edinburgh, Glasgow, Manchester, Leeds, Liverpool, Bradford, Birmingham and many others, have uselessly expended millions of money in attaining an ideally pure water supply, or that the people of London are running a great risk in continuing to depend almost entirely on the waters of the Thames and the Lea, which receive the more or less clarified sewage effluents of over a million and a quarter persons. And I am inclined to believe with the late Sir George Buchanan that large populations can continue to drink water which has been contaminated with apparent impunity, but that sooner or later such water takes upon itself morbific qualities which lead to death and disease.

Nearly connected with a pure water supply is pure air. This to some extent is insured by proper drainage and house sanitation, but it cannot be denied that the air of our large towns is far less pure than could be desired. And this to a large extent is no doubt due to the smoky atmosphere in which our town dwellers reside, and this when combined with mist and fog becomes at times one of the greatest evils from which our urban populations suffer.

As to the prevention of fogs, no doubt a great improvement is effected by proper drainage, but when towns or cities are situated in large river valleys, such as the Thames, and like London, one-tenth of which is situated on areas below high-water level, it is unreasonable to expect that fogs can be abolished. However, much can be done in the future to alleviate a great deal of the dirt and misery caused by a combination of fog and smoke, by a proper and more economical application of our fuel for heating purposes. As at present used the domestic fire in London, which burns coal in an open grate, is largely responsible for the contaminated state of the air; not only so, but it is a most wasteful mode of utilizing our fuel.

What really is required is a cheap and economical heating gas; at present, however, our gas manufacture being principally directed to produce a pure gas of high illuminating power, owing to its expense is in most cases a bar to its utilization for heating purposes. However, it is not an impossibility to produce a cheap gas of great heating power, but of low illuminating efficiency, which latter can be increased by the use of proper incandescent mantles. Nor is this an imaginary or ideal conception, for in the present Session of Parliament one of our largest London gas companies has obtained power to purchase 120 acres of land for the purpose, as stated by their chairman, Sir George Livesey, of carrying out a system of gas manufacture such as that I have above described. With electricity for the internal illumination of our houses, with gas fuel instead of the crude coal for heating and cooking purposes, and a cheap incandescent gas lamp for street use, I feel certain a great improvement could be made in the air breathed by our urban populations.

One of the greatest evils of our modern town life is the crowding together in congested areas of vast masses of the less affluent members of the community, and unfortunately owing to their circumstances they are unable to live in any but the poorest tenements. The difficulties which surround this problem are due in great part to the large rise in the value of land in our great towns, owing to that aggregation of population the evils of which we desire to avoid. But perhaps we may draw a lesson and see how this problem of increased urban land value versus dense population, is working itself out in a class somewhat above the poorest.

The City of London, properly so called, and the districts of Holborn and the Strand, as an example, were formerly thickly inhabited by traders and tradespeople, together with the vast commercial population which follows commercial life. Within the last fifty years, however, so enhanced has become the value of land and houses for purely business and commercial purposes that the former residents have found it impossible to reside in those districts and more economical to migrate to suburban areas; consequently our census returns show us that the resident population in the City, Holborn and the Strand is rapidly decreasing. The consideration of these facts at once points to the conclusion that some means of transit must be afforded for the workers, who are employed in our centers of commercial industry during the day, to their places of residence in the suburbs.

Much has already been done by the provision of railways and tramways to meet modern requirements, but I think that the lesson that we have to study in the future in dealing with this question is the dispersal of our redundant population over larger areas, and the removal, as far as practicable, of our manufactories from our towns into the country. This latter with our improved telegraphic and telephonic communication should not be impossible of achievement, and may even prove an economy to the manufacturer by locating his works in districts where land is cheap, which would allow of the construction on an enlarged area of more healthy dwellings for the laboring population.

The dispersal of our London population in the manner above suggested has been well illustrated during the past few years by the result of the working of the Central London Electric Railway and the Electric Tramways, which extend from its western extremity towards Hounslow, Isleworth and Uxbridge. An investigation of the low fares at which our working population can travel by this route, together with the fact that the Central London Railway alone is able to pay its shareholders 4 per cent. per annum on their investments, should prove an encouragement to other persons to do likewise. But when we have done our utmost to disperse our population as far as practicable, there will always remain a very large proportion of workers who must from the nature of their occupations reside on or near the site of their labors, and for their accommodation improved dwellings must be provided, and we have in London in the Boundary Street area, opened some years ago by the King and Queen, and in the new buildings being erected at Millbank by the London County Council, examples of what can be done to improve the habitations of our laboring classes.

In the above remarks I have briefly touched upon what have been the great improvements in the past, and on the various topics which to my mind deserve attention in the future. This is not the time to dilate upon the details connected with these various subjects, even were I qualified to grapple with them. To attain, however, the desired ends, I consider that much could be done if all these subjects touching upon municipal life, such as drainage, water supply, gas supply, housing problems and transit, were left more fuly in the hands of the governing bodies of our large municipal towns. These bodies are elected by the public suffrages of the ratepayers; they are representative in the fullest sense of the word, and their members are all of them (and I have had a life-long experience of our municipal bodies), fully competent to deal with these subjects, and could do so, I feel confident, were they relieved from many of the restrictions now placed upon them by our sanitary legislation. Could this be effected not only would a great advance be made in the carrying out of these important sanitary improvements, but the Imperial Parliament would be relieved of a vast amount of work now pressing upon our legislature. I cannot conceive a greater waste of energy and valuable time, which could be devoted to matters of higher national concern, than to see committees of Parliament and the House of Commons discussing for hours and days matters of purely local interest, of which its members can have in most cases little knowledge and still less interest. I feel strongly as an old municipal officer that more is to be gained by giving a free hand in all these matters to our local governing bodies and county councils, than in devising new sanitary legislation, which unfortunately appears to hinder rather than expedite the great objects which we all have in view.

The American Society of Municipal Improvements will meet at Rochester October 7, 8 and 9. In addition to important committee reports and descriptions of public works in Rochester, a long list of papers will be presented, some of which are the following: "Residential Septic Tanks," Burton J. Ashley; "Sewer Maintenance," John H. Emigh; "Practical Operation of Sewage Purification Plants," John W. Alvord; "Description of Interesting Sewer Construction in Brooklyn," Henry R. Asserson; "Street Cleaning," J. Herbert Grant; "Economic Theory of Municipal Lighting," Nicholas S. Hill, Jr.; "Cost of Pavements and Roads in Small Towns," Emmet J. Steece.

Letters to the Editor.

Unreasonable Contract Requirements by the Government.

Sir:—In the same issue of The Engineering Record (Sept. 20, 1902) which contains your article entitled "Unreasonable Contract Requirements by the Government," there appears in another column a list of the bids received by the Bureau of Yards and Docks for the construction of the dry dock at Norfolk, Va. The six bids range from $1,214,677 to $1,320,000, averaging $1,265,000. The appropriation for the work for which bids were received was $850,000, or $415,000 less than the average of bids received. In other words, the average contractor's estimate of doing the work under the specifications and plans, which were very similar to those for the Charleston dock, was 49 per cent. greater than the engineer's estimate. It seems to me that this confirms the statements made in your criticism of the result of inviting bids on such inadequate and unreasonable specifications. M. C. H.

The High-Level Bridge, Newcastle.

Sir:—One of the engineering achievements that attracts the attention of a visitor in England is the high-level bridge at Newcastle-on-Tyne, connecting Newcastle and Gateshead. Designed by Robert Stevenson and built more than fifty years ago, it stands a magnificent monument to his great engineering abilities. In comparison with modern bridges it still maintains a high place in the scale. It is unique in that the main compression members—the arches—are cast-iron. Through the kindness of Mr. J. W. Walker, managing director of Robert Stevenson & Co., Ltd., the following description of the bridge was obtained. The picture showing two of the spans was taken by myself with a pocket kodak from the top of a tottering lumber pile alongside the river. Believing the description and picture of sufficient interest to warrant their publication, I am sending them to you.

Yours truly,

Forrest R. Jones.

Birmingham, Sept. 1, 1902.

Old High-Level Bridge.—Contract let August 17, 1846; bridge completed August 14, 1849; open for traffic, February, 1850.

The width of the river at the point where the bridge crosses the Tyne is 515 feet. There are five piers 138 feet 10 inches apart, center to center. These piers are built of a hard, durable sandstone obtained from quarries in the neighboring coal formation. They are built on piles, the spaces between which are filled up with concrete. The majority of these piles are 40 feet long and all are driven through the hard sand and gravel forming the bed of the river till they reach the solid rock below; the piles are 13 inches square, and are placed 4 feet apart from center to center. The greatest weight that can come upon each is 70 tons, supposing none to be carried by the intervening spaces of concrete. This is considered a very heavy load, which could only be warranted by the goodness of the strata into which the piles are driven. In moderately compact clay it is usual to consider the maximum bearing power of a pile 12 tons, in hard clay 25 tons, but in gravel, of which the Tyne consists, 70 or 80 tons are often allowed. Many engineers consider the bearing power in such strata only limited by the resistance of the fiber of the timber. In this case the piles rest on the solid rock, which puts all doubt at rest as regards stability. In fact, one of these piles was tested to 150 tons, which was allowed to remain for several days, but no settlement whatever took place.

The masonry of the piers commences about 2 feet below low-water level, the lower portion being provided with cut-waters. The foundation surface of each pier is about 76.5x22.5 feet; the section of the tall shaft of the pier is about 46x14 feet, lightened by an arched opening 12 feet wide.

The High-Level Bridge, Newcastle.

Each span or bay is crossed by four main girders, the chief feature of each girder consisting of a cast-iron arch or bow, the ends of which are connected together and the thrusts taken by a wrought-iron tension rod or tie. The rise of the cast-iron arch is 17.5 feet, or a little less than one-seventh of the span. It is made in five segments strongly bolted and accurately fitted together, the depth at the crown being 3 feet 6 inches. The section is that of a double-flanged girder having 133 square inches area of metal in the two outer girders, and 189 square inches in the inner ones, which have more weight to support. The tension ties or strings of the bow consist of flat wrought-iron bars 7x1 inch, each outer girder being tied by four of these and each internal girder by eight. The girders are all strongly braced together with diagonal frames.

The railway platform is placed above the top of the arches, a series of pillars being carried up throughout the spandrels so as to support entablature beams lying horizontally above them the whole length of the bridge. Cast-iron cross bearers rest on these, extending in one length over the four main girders. These again support longitudinal timber joists on which a flooring of double diagonal planking jointed and tongued with hoop iron and well caulked with pitch is laid. The three lines of rails are fastened down to the planking in the ordinary way. The lower roadway for common traffic is hung from the arches by wrought iron suspending rods bearing longitudinal beams similar to those on the top platform, and upon these cross bearers rest carrying a double-plank roadway in like manner. This is paved with wood blocks set in pitch and covered with sand and gravel. The four girders are placed to leave room for a carriage way 20 feet wide and the two footways are 6 feet each. The total width of the bridge from outside to outside is 46 feet.

Provision is made for the expansion and contraction of the iron superstructure by fixing the girders firmly to the first, middle and fifth piers, and making them free to move on the second and fourth, as well as on both the abutments. There are no rollers; the bearings have surfaces fitted for sliding on each other. The motion caused by a variation of 32 degrees temperature was found by experiment to be 0.153 of an inch for each span.

As far as the construction of the bridge was concerned the mixture employed for the principal parts, viz., the arch, ribs and transverse girders, was selected from the following mixtures:

	Cwts.
Ystalifera Anthracite No. 3	40
Resdale Hot Blast No. 3	40
Crawshay (Welsh) Coal Blast No. 1	40
Blaenavon Cold Blast No. 1	30
Coalbrook Dale Cold Blast No. 1	30
Selected Scrap	30

The total weight of the cast-iron employed was 4.728½ tons. The amount of wrought-iron was 321½ tons. The total quantity of masonry employed was 686,000 cubic feet.

The total length of the bridge is 1,337 feet; the height from high water to carriage way, 85 feet; height from high water to rails, 112 feet. The cost of the bridge was as follows: Bridge, £243,096; approaches, £113,057; land, compensation, etc., £135,000; total, £491,153.

A Double Water Tower.

Sir:—The Board of Trustees of the Ohio Soldiers' and Sailors' Orphans' Home near Xenia have recently accepted the water tower erected at that place this summer at a cost of $6,000. This tower differs in some respects from other towers, in that there are two tanks, one inside of the other. One is for hard water and the inside tank for soft water, each to hold 1,000 barrels. The foundations consist of four stone pillars, 8 feet square at the base, 3 feet square at the top and 6 feet high. Upon these rest four columns 68½ feet high, and on these are the girders which hold the tank, which is 35 feet high and 18 feet in diameter. The inside tank is 12 feet in diameter. The first 10 feet is ⅜-inch steel, the second 10 feet 5/16-inch, the next 15 feet ¼-inch. This is surmounted by an ornamental steel cover.

At the base of the tank, 68 feet from the ground, is a walk 4 feet wide, with concrete floor 4 inches thick at the tank and 2 inches thick at the outside of the guard rail. From the bottom of the tank are connected three pipes, one for hard water, one for soft water and an overflow pipe, which conveys the waste water to an artificial lake, which keeps it fresh.

When the tank was first tested, water was pumped into the outside tank, leaving the inner one empty, and while doing so the inside tank collapsed and had to be taken apart and shipped to Dayton to be reconstructed. There is a difference of opinion as to the cause of this accident. One engineer says it was caused by not calking the seams on a swinging staging. The staging was made the whole width of the outside tank, and when the wood swelled the inner tank sprung. Another says that the water being pumped into the outside tank commenced to swirl rapidly, and as this continued the tank commenced to swing in the direction of the current, which caused the trouble.

They have now put in 48 braces from the inner to the outer tank, held to each by angle plates and two bolts. The braces are made to allow for expansion and contraction. The tower was then accepted by the board.

This tower was built to take the place of a brick one 87 feet high, which had four tanks and held 580 barrels of water. This was constructed thirty-one years ago and collapsed in April, 1901. A singular thing about the old tower was that it did not topple over, but crumbled in almost the space it occupied on the ground.

Yours truly, George F. Cooper,
Genl. Manager, Water Works.
Xenia, September 17.

Book Notes.

The popularity of the writings of Dr. Samuel Rideal on chemical and biological subjects relating to sanitary engineering is demonstrated by the appearance of new editions of two of his books. One of these, "Water and Its Purification," is published by the J. B. Lippincott Co., Philadelphia. It is a 350-page volume on the characteristics of natural waters, animal and vegetable impurities, the different classes of water, storage, distribution, water purification on a large scale and in the household, water softening, and water analysis and the interpretation of results. The additions in the new edition relate to recent epidemics of water-borne diseases and to sand filtration. The author's experience as analyst for public boards in Great Britain renders his remarks of more practical engineering value than is usually the case with the sanitary publications of chemists, and in spite of some statements which seem strange to the American reader, the book is one full of useful data for health officers and water-works officials. His second volume is the treatise on "Sewage and the Bacterial Purification of Sewage," published at $3.50 by John Wiley & Sons, New York, the first edition of which was noticed so recently that an extended review is unnecessary. It is indispensable to those desirous of obtaining a clear conception of the changes that occur in sewage during its mutations into innocuous substances. The new edition is marked by the revision of some misleading statements in the first edition and by the addition of new data on both theoretical and practical subjects.

Another work on sewerage which deserves careful study is Mr. Gilbert J. Fowler's "Sewage Works Analyses," published at $2 by John Wiley & Sons, New York. The author's long experience as the superintendent and chemist of the sewage disposal works of Manchester, England, has made him an authority on the subject. While the work is mainly chemical, as the title implies, the engineer will find no small part of it valuable as indicating the reasons for certain classes of analysis and explaining the meaning of the results.

Still another book on sanitary subjects is Dr. William T. Sedgwick's "Principles of Sanitary Science and the Public Health," published at $3 by the Macmillan Co., New York. The author needs no introduction to the readers of The Engineering Record, for his good work in reducing hygiene to sanitary science is well known to its readers. It may not be known, however, that his technical writings are marked by a vigor and happy gift of expression which lifts them far above the plane of dull accuracy on which such works rest so firmly and solidly. The book is in two parts, of which the first is a general discussion of the conceptions of health and disease. The nature of the vital machinery is explained, the various theories of disease are traced in their historical order, and the wonderful teachings of bacteriology are outlined. The second part is an outline of so much of hygiene as may safely be called sanitary science. That is to say, there are chapters on infection and contagion, dirt and disease, sewage, water, ice, milk and food as vehicles of infectious diseases, and the prevention, inhibition and removal of infection. There are few subjects which ought to receive more attention from citizens than these, for it is not legislation so much as education that is needed to improve the general tone of health of our towns.

A book in which conciseness and accuracy of statement are materially assisted by excellent illustrations, many of unique interest, is "City Roads and Pavements," by Mr. William Pierson Judson, M. Am. Soc. C. E. It is intended to supply information useful mainly in cities of moderate size, and is wholly free from padding of any sort, which makes it a good textbook for schools as well as a practical manual for the officials of cities and villages. The preparation of streets for pavements, the construction of concrete foundations, and the relative merits and methods of laying stone block, wood, brick and asphalt are fully explained. The information is such as an engineer will find really useful, and the figures of cost of work are fair averages. In the section on foundations, the author supplies directions for simple cement tests with an outfit costing not over $4 and giving results which will reject no good cements but will keep out poor material. The detailed and practical directions for making monolithic concrete include valuable features of actual good practice which are not known to be elsewhere published. The chapters on telford and macadam road building form by all odds the most practical and useful collection of data on the subject with which this journal is acquainted. In the author's endeavor to be concise, he has perhaps stated without qualification opinions on a few disputed features of street and road work which some engineers will question, but in such matters his views are those of most road experts except as regards granite block pavements. His condemnation of these is too sweeping, as they give excellent streets at a fairly low cost in parts of the country where the blocks are prepared at local quarries. The book is sold for the author at $2 by Engineering News, New York.

Although Pierre Simon, Marquis de Laplace, may have been a political sycophant, as a mathematician his work reached the highest plane of originality. His greatest work was unquestionably in the application of mathematical analysis to astronomical problems, where, spurred by friendly rivalry with Lagrange, he made a succession of brilliant demonstrations which only ceased when no more problems worthy of his attention remained unsolved. His work in other lines was equally important, and that in the theory of probabilities has been of great practical value. His "Analytical Theory of Probabilities" is a treatise which can only be grasped by the ablest mathematicians, but they have interpreted and expanded it in their works so that it is available at second hand. It is characteristic of Laplace's genius, however, that when he wished to express the results of his studies in simple form for the general public, the result was always a lucid essay of the most interesting character. "The theory of probabilities," in his eyes, "is at bottom only common sense reduced to calculus; it makes us appreciate with exactitude that which exact minds feel by a sort of instinct without being able oftentimes to give a reason for it. It leaves no arbitrariness in the choice of opinions and sides to be taken; and by its use can always be determined the most advantageous choice." These views were explained in one of the most pleasing essays on a mathematical subject which was ever written. A translation of the sixth French edition has recently been made by Profs. F. W. Truscott and F. L. Emory under the title "A Philosophical Essay on Probabilities," which is published by John Wiley & Sons, New York. It will undoubtedly prove useful to a large circle of readers unable to secure a copy of the French edition.

Another mathematical essay which it is a pleasure to see rescued from the oblivion of bibliographies is "The Study of Mathematics," by Augustus De Morgan. The author was one of the great mathematicians of the last century, and the first English writer to insist on the strict logical development of analytical processes. He was truly a prophet crying in the wilderness of the mathematical world, and for a long time his protests against the current views passed unheeded. But to-day all is changed, and it is interesting to notice how closely the workers in the line of mathematical logic are following out the plans sketched by him fifty years ago. His great aim was to show that the most logical proof of a proposition was the simplest to understand when properly presented, and many of his writings were intended to raise the standard of instruction in elementary subjects. In the book mentioned, for example, he shows how the development of arithmetic, algebra and geometry can be taught without any of the mechanical severity of the methods in common use, yet with a rigorous regard for logic that leaves nothing to be desired. It is one of his best and most useful essays, and is published by the Open Court Publishing Co., Chicago, at a price, $1.25, which is very low for a mathematical book of nearly 300 pages. The same publishers have also brought out a new edition of Mr. T. J. McCormack's translation of Mach's "Science of Mechanics." This well-known critical and historical account of the development of the science has met with a remarkable reception from the leading mechanical specialists of Europe and this country, while its general popularity is evident from the numerous editions which have been issued. Its aim is to show how the principles of mechanics have been worked out slowly from the first rude theories and crude experiments, through mathematical analysis and careful investigation, into the form they now possess. The various steps in the development, told in places in the quaint language of the past and illustrated by the rude woodcuts of rare volumes two or three centuries old, serve to fix the basic facts of mechanics in the mind with a firmness which other methods often lack. The new English edition contains the extensive additions made by Professor Mach to the German editions and differs from them only in one short section on units and measures. Here, with the author's consent, Mr. Charles S. Peirce has rewritten a number of pages in order to make the treatment applicable to the system commonly taught in this country. The work is a well-illustrated 600-page volume and is sold at $2.

The third bulletin of the University of Texas Mineral Survey is a profusely illustrated 138-page book covering the following subjects: Chapter I, location of coal and lignite mines and character of output; Chapter II, the financial and technical values of Texas coals and lignites; Chapter III, the asphalt rocks of Texas; Chapter IV, the uses of asphalt and asphalt rocks; Chapter V, the chemistry of some of the Texas asphalt rocks. The last chapter is by Dr. H. W. Harper and the others by Dr. W. B. Phillips, director of the Survey. It is hardly necessary to refer to the general interest in the portions of the report relating to the Texas asphalt rocks, which have been used successfully in laying large areas of pavements in a number of cities, of which useful data are given. Copies of the bulletin can doubtless be obtained by addressing Dr. Phillips at Austin.

A classified list of makers of machine tools and metal-working machinery is being issued by the Industrial Press, New York. Section A, a 159-page pamphlet sold at $1, gives the names and addresses of makers of bicycle machinery, blacksmiths' tools and appliances, bolt and nut machinery, machine tools and accessories, machinists' small tools, metal-working machinery, wire-making apparatus. There are English, German and Spanish indexes to the numerous classes of tools and appliances under which the firms are listed.

"A Graphic Method for Solving Certain Questions in Arithmetic or Algebra," one of the Van Nostrand Science Series by Prof. George L. Vose, has reached a second edition. It makes use in an ingenious manner of the principle of the train sheet as applied in railroad offices, to the solving of many mathematical problems. The method is simple and effective, and affords a convenient mode of obtaining a comprehensive view of several complex problems. It is published at 50 cents by the D. Van Nostrand Company, New York.

Personal and Obituary Notes.

Mr. S. H. Kupp has resigned as city engineer of Carbondale, Pa.

Mr. Howard Smith has been elected city civil engineer of Rochelle, Ill.

Capt. J. H. McRee, State engineer of North Carolina, died September 9 of apoplexy, at Lumberton, N. C., at the age of about 50 years.

Mr. D. Everett Waid, of New York City, has been commissioned architect to the Bond and Mortgage Division of the Metropolitan Life Insurance Company.

Mr. W. G. A. Millar, formerly manager of the ornamental department of the American Bridge Co., has been appointed purchasing agent of the company with offices at 259 South Fourth St., Philadelphia.

Mr. James J. Ryan, formerly city engineer of Muscatine, Ia., and Mr. James E. Bradford, have formed a partnership for general engineering work with an office in the Olds Opera House Block, Muscatine.

Lieut. R. E. Peary, civil engineer, U. S. N., has been promoted to the rank of commander. Since 1881, when he entered the service of the navy, he has spent all but about four years in Arctic exploration.

Mr. Alexander C. Humphreys, who recently accepted the presidency of Stevens Institute tendered him several months ago, has begun his administration with the largest freshman class in the school's history.

Mr. W. B. Hampson, a graduate of Purdue University in 1893, and for five years instructor of mechanical engineering at the University of Nebraska, has assumed new duties as professor in engineering at the University of Washington, Seattle.

Mr. J. E. Willoughby has been appointed chief engineer of the Knoxville, LaFollette & Jellico Railroad, succeeding Prof. W. D. Taylor, who has returned to the University of Wisconsin to resume his work as professor of railway engineering.

Thomas Frazer, at one time resident engineer of the Michigan Central Railroad, and later general agent and paymaster, died September 23 at Detroit at the age of 88 years. He was engaged in the thirties as a civil engineer in laying out the Lake Shore & Michigan Southern Railroad.

Mr. F. M. Marsh, for five years chief engineer of the Fremont, Elkhorn & Missouri Valley Railroad, has resigned to accept a position as assistant to chief engineer J. B. Berry, of the Union Pacific Railroad. Mr. A. A. Schenck, division engineer of the Chicago & North Western Railway, at Boone, Ia., has been appointed to the vacancy.

Josiah D. Cook died of apoplexy at his home in Toledo, O., on September 17. He was born on April 26, 1830, in Warren County, Va., served in the Civil War, and, resuming engineering work at its close, in 1873, he became chief engineer of the Smith Bridge Co., Toledo. He is best known as a water-works engineer, having designed and constructed water-works plants in some 63 cities in the United States, among them being Toledo, Sandusky, and Galveston, Tex.

Mr. E. A. Bond, M. Am. Soc. C. E., has been renominated as the Republican candidate for the office of New York State Engineer and Surveyor. His engineering experience began in 1868 on the Lackawanna Railroad. Two years later he joined the staff of the Utica & Black River Railroad, of which he was soon appointed chief engineer. From 1886 to 1889 he was chief engineer of the Carthage & Adirondack Railway, resigning in the latter year to become a member of the engineering firm of Hinds & Bond, with offices in Watertown.

Charles H. Latrobe died September 19 in Baltimore at the age of 69 years. He was graduated from St. Mary's College and began his career with the Baltimore & Ohio Railroad. After the Civil War, in which he served in with the Confederate Army, he entered the practice of civil engineering in Baltimore, where for nearly 30 years he had charge of, or was engaged in city improvements. Among his more important works, perhaps, were the walling in Jones' Falls, and laying out Mount Royal Avenue. He was also consulting engineer for a number of railroads, including important work in the Andes in Peru.

Maj. J. W. Powell, director of the Bureau of Ethnology at the Smithsonian Institution, at Washington, died at his summer home at Haven, Me., September 23. He was born in Mount Morris, N. Y., in 1834, but spent the early part of his life in Illinois, Wisconsin and Iowa, where he developed a fondness for the natural sciences. He served during the Civil War, enlisting as a private and becoming a major. At its close he was made professor of geology at Illinois Wesleyan University, and since that time has conducted many exploring parties, given many lectures and done considerable writing along his chosen field. He is said to have been the first man who ever went through the Colorado Canyon. He was regarded by many scientists in Washington as in the foremost rank of the geologists and anthropologists of the world. He received the degree of Ph.D. from Heidelberg and LL.D. from Harvard, and in 1887 was president of the American Association for the Advancement of Science.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see pages xv, xvi, xviii and xxvii.

WATER.

Tonawanda, N. Y.—Bids will be received by the Village Municipal Bd. until Oct. 14 for pumping engines, as advertised in The Engineering Record.

Brockton, Mass.—Bids are wanted Nov. 8 for furnishing and erecting complete one (6,000,000-gal. daily capacity) pumping engine, as advertised in The Engineering Record.

Long Branch, N. J.—The Home Water Co., recently organized with a capital of $100,000, is reported to have accepted the terms of a 10-year contract to serve this city with water for all municipal purposes. Incorporators: Louis Rothenberg, B. P. Morris, and others.

Brooklyn, N. Y.—The construction of 3 pumping stations which when completed will increase the water supply of this city by from 10,000,000 to 12,000,000 gals. per day, was recently authorized by the Bd. of Aldermen and plans for same are now being prepared by the Engrs. of the Brooklyn Water Dept. Total estimated cost, $154,000.

Brooklyn, N. Y.—Bids are wanted Oct. 9 for furnishing material and delivering, erecting and connecting a new boiler at the Mt. Prospect Pumping Station, Boro. of Brooklyn. Robt. Grier Monroe, Comr. Water Supply, Gas & Electricity.

Pittsburg, Pa.—Local press reports state that the National Water Works & Guarantee Co., of Pittsburg, has started to absorb the water companies supplying many towns in western Pa., by the purchase of the Latrobe Water Co. at a reported price of $400,000. W. A. Johnson, Mgr. of the system, will, it is stated, retain his position under the new ownership. The Latrobe Co. drew its supply from the headwaters of the Loyalhanna, and it is reported that the system operated from this watershed will be largely increased, and many other towns and hamlets in that vicinity supplied.

Altoona, Pa.—City Engr. Harvey Linton writes that the Altoona Water Dept. has employed C. W. Knight to make a survey of Tipton Run watershed, for an additional water supply.

Oneida, N. Y.—The Bd. of Pub. Wks. has instructed City Engr. Vedder to prepare plans and specifications for a new cement spillway at the storage reservoir of the water works system

Philadelphia, Pa.—The contract to build, at Race St. and Delaware Ave. a pumping station for the special fire main service has been awarded by Dir. of Pub. Wks. Haddock to Henderson & Co., for $56,533, to complete the work in 180 days.

The contract for building engine and boiler house No. 2 of the pumping station at Lardner's Point near the Forresdale filtration plant, has been awarded to Geo. C. Dietrich for $532,000, to complete the work in 240 days.

The contract for laying a 20-in. water main on Water St. has been awarded to the Hoffman Engineering Co. for $35,000.

Ogdensburg, N. Y.—The Com. (Thos. Spratt, Chmn.) which was appointed by Mayor Geo. Hall to investigate and report to the Water Sewerage Comn. the causes of the overflow of Oswegatchie River from Gouverneur to the River St. Lawrence in Ogdensburg, and the Indian River from Theresa to the head of Black Lake, has reported recommending the construction of a dam at a point known as the Eel Weir; also that the present reservoir at Cranberry Lake be enlarged by raising the dam and putting in proper gates and bulkheads; the committee also suggests that a reservoir be constructed near Harrisville on the west branch of Oswegatchie River.

East Rutherford, N. J.—The Water Com. has reported in favor of the construction of a municipal system of water works at an estimated cost of $48,000. The proposed system includes 8 miles of 10 to 4-in. pipe, 50 hydrants, and 220 10 to 4-in. gates, with driven wells, 2 engines and 2 pumps, standpipe, etc.

Jersey City, N. J.—The New Jersey Suburban Water Co., Jersey City, has been incorporated, with a capital of $100,000. Incorporators: Frank Koch, Jos. Odell, Horace S. Gould and Kenneth K. McLaren, Jersey City.

Bridgeport, Conn.—The Bd. of Health has recommended that the Bridgeport Hydraulic Co. be directed to install a system of filtration for the city's water supply.

Rochester, N. Y.—The Joint Com. of the Finance and Water Works Com. has reported recommending the adoption of the ordinance authorizing the Comr. of Pub. Wks. to acquire land on Cobb's Hill, for a 7,000,000-gal. reservoir. Estimated cost of land, reservoir and pipe, $682,000.

Philadelphia, Pa.—Local press reports state that the only bid received Sept. 23 for installing preliminary filters at the Lower Roxborough plant was from the Maignen Filtration Co., of Philadelphia; their bid, which was as follows, covered the furnishing of rough filters guaranteed to pass 12,000,000 gal. a day of partly filtered water into the sand filters: $49,800 to rough filter the water at the rate of 1,377 gals. a sq. ft. a day, and $69,500 at the rate of 2,066 a sq. ft.

Paulsboro, N. J.—Bids are wanted Oct. 11 for 330 short tons of 8, 6 and 4-in. cast-iron pipe; 10 net tons of special castings; 21 8-in., 6-in. and 4-in. stop valves, with boxes and covers; 41 4-in. double nozzle fire hydrants; steel standpipe, 12 ft.x100 ft.; stone foundation for standpipe; brick power house, and triplex pumping machinery and gasoline engine. Wm. J. Adamson, Secy., Paulsboro Water Co.; Isaac S. Cassin, Jr., Consulting Engr., Philadelphia, Pa.

Carthage, N. Y.—Eaton & Brownell, of Carthage, are said to be making surveys for the proposed water and sewer system for this village.

Martinsburg, W. Va.—City Clk. A. F. Lambert writes that the matter of improving the water works is being considered, but no definite steps have as yet been taken.

Chester, S. C.—Bonds are reported to have been voted for the construction of water works.

Clarksburg, W. Va.—A charter has been granted to the Steelton Land Co., of this city, for the purpose of dealing in real estate, building houses, water-works, etc. The authorized capital is $750,000, and the incorporators are T. G. Brady, J. M. Crouch, E. R. Davis, and others, of this city.

Big Stone Gap, Va.—An election will be held in Oct. to vote on the issue of $20,000 bonds for street improvements and for increasing the water supply.

Moline, Ill.—Bids are wanted Oct. 29 for furnishing work and material for the improvement of the city water works system, as advertised in The Engineering Record.

Webster Groves, Mo.—Through error an item calling for bids (to be opened Oct. 6) for 940 net tons of 12 to 4-in. pipe and 12½ net tons of special castings, delivered f. o. b., Webster Groves, appeared last week in The Engineering Record under Webster Groves, O., instead of Webster Groves, Mo. Wm. H. Bryan, Consulting Engr., 706 Lincoln Trust Bldg., St. Louis, Mo. Edw. S. Hart, Chmn. Com. on Water Supply, Clayton, Mo.

North Milwaukee, Wis.—Village Clk. W. E. Chase writes that the following bids were opened Sept. 19 for furnishing 466 tons of 4, 6 and 8-in. iron water pipe; prices are per net ton; M. J. Drummond & Co., New York City, $33.45; J. B. Clow & Sons, Chicago, Ill., $36.75; U. S. Cast-Iron Pipe & Fdy. Co., Chicago, $34.75.

New London, Wis.—Geo. Cadogan Morgan, Hydraulic Engr., 808 Royal Insurance Bldg., Chicago, Ill., writes that contracts for machinery, supplies, etc., for a water works plant, f. o. b. cars, New London, have been awarded as follows (bids opened Aug. 28): Deane Steam Pump Co., Holyoke, Mass., pumping machinery, $999; Fairbanks, Morse & Co., Chicago, boiler, etc., $696; Stilwell-Bierce & Smith-Vaile Co., Dayton, O., heater, $210; U. S. Cast-Iron Pipe & Fdy. Co., Chicago, Ill., pipe and special castings at $33.60 per ton for 8 and 10-in.; $34.60 per ton for 6-in.; $36.60 for 4-in. and 3 cts. per lb. for specials. Rensselaer Mfg. Co., Troy, N. Y., hydrants, valves and boxes, $1,435; Ft. Wayne Fdy. & Mch. Co., Ft. Wayne, Ind., standpipe, steel work erected, $2,700. All other materials purchased in detail and home labor employed to do the work. Total cost about $35,000.

Findlay, O.—Bids are wanted until Oct. 7 for water works extension improvements: approximate quantities 4,200 tons of 20-in. iron pipe at 1,875 lbs. per 12-ft. length, 126 tons 8-in. iron pipe at 504 lbs. per 12-ft. length, 15 tons of special castings, 56,000 ft. 24-in. double strength vitrified pipe, and 1 receiving basin, average cut 7½ ft. Wm. Demland, Secy. Bd. of W. W. Trus. John W. S. Riegle, City Engr.

Jacksonville, Ill.—The City Council has passed an ordinance which will lease the present water plant for 30 years to F. W. Mayhon and others, of Chicago; the lessees are agreed to lay a pipe line to the Illinois River, 20 miles away, and use driven wells as a source of supply. The work proposed will cost $500,000, according to local press reports.

Kansas City, Mo.—The Bd. of Pub. Wks. is stated to have accepted the bid of the Barr Pumping Engine Co., of Philadelphia, to furnish the city with a vertical triple expansion pumping engine to be set upon foundations built by the city and to be ready for use within 8 months; capacity of engine, 15,000,000 gal. per day; price, $130,500.

Springfield, O.—The City Council has sold $30,000 water works bonds.

Harshaw, Wis.—A water works system is said to be projected.

Steubenville, O.—The Water Works Trus. have been authorized to purchase a tract of land for the proposed low pressure reservoir to furnish an additional water supply of 3,000,000 gal.

St. Paul, Minn.—Judge Giddings has appointed a commission to condemn lands in Anoka Co., wanted by the Bd. of Water Comrs.; said Bd. is desirous of securing about 200 acres of land adjacent to Peltier and Centerville Lakes, for the purpose of constructing a reservoir and putting in a dam at the outlet of Peltier Lake.

Evanston, Ill.—The City Council has passed an ordinance providing for the construction of a system of 4-in. cast iron water mains in Washington Place and Wesley Ave.

Mishawaka, Ind.—Mayor Mix has recommended to the Council the installation of water meters, and the employment of Mr. Walker, of Flint, Mich., to investigate the situation here for the purpose of locating the artesian strata.

Grinnell, Ia.—H. F. Lanphere, Secy., writes that the Grinnell Water Co. has awarded the contract for water works to the Des Moines Bridge & Iron Wks., of Des Moines, Ia.

Westbrook, Minn.—Village Recorder John E. Villa writes that M. B. Haynes, of Mankato, Minn., is the Engr. in Charge of proposed water works system, to be built at a cost of $7,000.

Cadillac, Mich.—This city has granted to Jacob Cummer, Wellington W. Cummer, Delos F. Diggins and others a 25-year franchise to maintain and operate water works, electric light and power plants.

Bowling Green, O.—Local press reports state that the new water company proposes to enlarge the plant, put in pipe extension and drill several new 10-in. wells.

Houma, La.—Hydraulic Engr. Geo. C. Morgan, 808 Royal Insurance Bldg., Chicago, Ill., writes that contracts for the construction of the water works (bids opened Sept. 9) have been awarded as follows: Fairbanks, Morse & Co., Chicago, Ill., pumping machinery, f. o. b. cars Houma, $635; Henny & Castanedo, New Orleans, boilers and heater, $932; Washington Steam Boiler Wks., Chicago, Ill., steel work of water tower erected, $1,713; Dimmick Pipe Co., Birmingham, Ala., cast-iron pipe and specials, f. o. b. Houma, at $37 per ton for pipe, specials 3¼ cts. per lb.; Rensselaer Mfg. Co., Troy, N. Y., hydrants, valves and boxes, $1,450; all other materials to be purchased of local parties and home labor will be employed to construct work. Total cost, $27,000.

Sherman, Tex.—Press reports state that bids will be received by the City Council until Oct. 6 for $50,000 water and sewer extension bonds.

Marshall, Tex.—Press reports state that this city will put in a new standpipe and purchase a boiler for the water plant. T. D. Ledbury, Secy.

Mena, Ark.—This city is reported to have voted $25,000 water works bonds.

Fayette, Miss.—Bids will be received at once by C. H. Jenks, Engr., Fayette, Miss., for sinking the following deep wells: At Terry, Miss., 1 6-in.; at Woodville, Miss., 1 7-in.; at St. Francisville, La., 1 8-in.; each to have 20 ft. of Cook strainer and guaranteed to supply not less than 100 gals. per minute. Price based upon a minimum depth of 300 ft. State in offer how soon work can be done.

Hobart, Okla. Ter.—Plans and specifications for the water works system for this city are being prepared by Burns & McDonnell, Postal Telegraph Bldg., Kansas City, Mo.

Colorado Springs, Colo.—City Clk. K. M. MacMillan, writes that bids will be wanted when plans are completed (probably in a few weeks) for the reservoir to be constructed for the water works at a cost of $75,000. E. W. Case, Engr. in Charge.

Dallas, Ore.—Bonds to the amount of $12,000 have been voted for municipal water works, and the contract for construction is stated to have been awarded to H. V. Gates.

Williston, N. D.—J. A. Johnson, of Fargo, has applied for a franchise for an electric light plant and water system.

Sterling, Colo.—The question of establishing a municipal system of water works is being considered by this city.

Tacoma, Wash.—The City Council has directed the Comr. of Pub. Wks. to ask for bids and let the contract for sinking a well and making a test of the air-lift system for the proposed new water plant at Edison to supply the city of Tacoma.

Walsenburg, Colo.—The Town Bd. has appointed a committee to investigate the water works question. The present Water Co. is willing to sell its plant for $50,000.

Salt Lake City, Utah.—The Mountain Home Irrigating Light & Power Co., of Salt Lake City, has filed articles of incorporation. Capital, $300,000. Geo. L. Nye, Pres.; W. J. Turner, Vice-Pres.; E. P. Sears, Secy., and A. G. Smith, Treas.

Florence, Colo.—The Colorado Fuel & Iron Co. is said to be making surveys for a line from Canon City to Beaver Creek for a canal about 50 miles long, which it is proposed to build in order to secure a more plentiful supply of water for the Minnequa Steel Wks., at Pueblo. Probable cost of canal and reservoirs, about $100,000.

Montreal, Que.—Local press reports state that certain boilers at the water works pumping station need to be replaced with new ones, and it is proposed to ask appropriations for new boilers and for the increase of the city's pumping capacity.

Torreon, Coahuila, Mex.—Press reports state that a concession has been granted by the State of Coahuila to Mackin & Dillon, of Monterey, Mex., for building the water works and sewerage system at Torreon, the estimated cost of which is from $300,000 to $400,000. Work is expected to be completed within 2 years.

SEWERAGE AND SEWAGE DISPOSAL.

Athol, Mass.—The contract for building 5 miles of sewer is reported to have been awarded to Long & Little, of Leominster, Mass., for $20,000.

Hanover, Pa.—The charter of the Hanover Sewer Co. has been entered for record. The company is formed for the purpose of laying pipes, conduits, sewers and erecting sewage disposal works, catch basins, etc., necessary to construct a sewer system and to maintain and operate same. Directors: John H. Cromie, Jr.; Hugh Robertson and J. H. McNeal, all of Philadelphia. Capital stock, $1,000.

Medford, Mass.—The Comrs. of Sewers have ordered the construction of a 30-in. circular masonry storm water sewer in 3 streets, with tide gates at the outlet, all work to be done under the direction of City Engr. Wm. Gavin Taylor.

Calcutta, India.—Fred Gainsford, Secy. to the Corporation of Calcutta, writes that the following bids were opened July 15, 1902, for furnishing and delivering pipe and specials:

Bidders.	Maker of Pipes, Etc.	Straight pipes, 2,688 tons.	Specials, 114 1/5 tons.	Totals.
D. M. Stevenson & Co., Glasgow	Cie Generale of Liege Belgium or first class British makers	$33.54	$58.73	$97,620
*Balmer Lawrie & Co., Calcutta	R. Maclaren & Co., Glasgow	34.32	54.72	98,345
Burn & Co., Howrah	D. Y. Stewart & Co., Glasgow	35.54	55.25	101,860
Martin & Co., Calcutta	Stanton & Co., Stavely & Co., Cochrane Grove & Co., Macfarlane Strang & Co	35.42	59.80	102,050
Jessop & Co., Calcutta	Macfarlane Strang & Co., Glasgow	38.60	59.40	111,080

*Contract awarded.

Westfield, Mass.—Local press reports state that Town Engr. O. E. Parks has about completed plans and specifications for the southern section of the surface drainage system.

East Orange, N. J.—The city officials are said to have arranged for the proposed completion of the 3d Ward drainage system.

Batavia, N. Y.—County Judge Washburn, attorney for the Bd. of Sewer Comrs., has filed with City Clk. Steele the final report of said Bn. for a permanent sewerage system for this village. Plans prepared for same, by J. W. Holmes. of Batavia, have been approved by the State Bd. of Health.

New London, Conn.—A survey of Ocean Beach is being made under the direction of the Sewer Bd. for the construction of a sewer.

West Carthage, N. Y.—The contract for constructing the sewer system is stated to have been awarded to Geo. S. Miller & Co., of Oneida, for $19,338.

Elizabeth, N. J.—Bids are wanted Oct. 1 for constructing sewers in certain streets. N. K. Thompson, St. Comr.

Dedham, Mass.—Bids are wanted Oct. 1 for $53,000 sewerage bonds. E. A. Brooks, Treas.

Brooklyn, N. Y.—Bids were opened Sept. 17 by the Boro. Pres. for constructing sewer crossings under Atlantic Ave. Improvement Subway, as follows:

Items.	John M. Waddle.	John O'Grady.
30-in. brick sewer, 2,300 ft	$8.25	$10.00
24-in. cast iron pipe, 36 ft	13.00	6.00
18-in. cast iron pipe, 108 ft	10.00	6.00
12-in. vit. pipe, 200 ft	3.50	1.75
30 manholes	88.00	100.00
Planking, 22 M. ft	35.00	18.00
Sheeting, 430 M. ft	35.00	18.00

Carthage, N. Y.—See "Water."

Skaneateles, N. Y.—By recommendation made by Engr. Olin H. Landreth and approved by State Health Comr. Lewis, the city of Syracuse is called upon to meet the expense of constructing a system of sewerage for the village of Skaneateles as a measure for preventing the pollution of the city water supply at Skaneateles Lake, the ownership to remain, however, with the village of Skaneateles.

Kenmore, N. Y.—A correspondent writes that the village of Kenmore is to have a system of sewerage, and that the Engrs. Dept., Buffalo, is preparing plans for same.

Watseka, Ill.—Press reports state that Iroquois, Ford and Livingston Counties will expend $100,000 on a new drainage ditch to prevent the recurrence of the annual floods.

Waukegan, Ill.—Bids are wanted Oct. 10 for the construction of a system of sanitary sewers, as advertised in The Engineering Record.

Lansing, Mich.—Bids for the construction of sewers in the 1st Ward have been rejected and action deferred until next spring. H. A. Collar, City Engr.

Grand Rapids, Mich.—The new date for receiving bids for the construction of a public sewer along the line of the West Side Ditch is Oct. 17, as advertised in The Engineering Record.

Dayton, O.—Bids will be received by the Bd. of City Affairs until Oct. 3 for constructing storm water sewers in portions of 4 streets, requiring approximately 840 lin. ft. of 42-in. brick or concrete sewer, 135 lin. ft. of 42-in. brick or cement sewer, and 2,976 lin. ft. of 24-in., 18-in., 15-in. and 12-in. pipe sewers, 25 catch basins, etc. Robt. H. Ferguson, City Compt.

Cincinnati, O.—Bids will be received by the Bd. of Pub. Service until Oct. 1 for furnishing material and constructing sewers and drains in portions of several streets; also until Oct. 15 for furnishing material and constructing a trunk sewer and drains, with appurtenances, in a portion of Lindwood Ave. Geo. F. Holmes, Clk.

Davenport, Ia.—Bids are wanted Sept. 30 for constructing sewers in several streets. Thos. Murray, City Engr.

Cleveland, O.—The following bids were opened Sept. 17 for sewer construction: for Spafford and other streets: W. J. Townsend bid $7,136; C. T. McCracker Co., $7,520; C. Burkhardt, $8,004; R. P. Burnett, $8,301; and John Potts Co., $8,795. For Wellington and other streets: C. Burkhardt bid $17,731; Reagh Const. Co., $18,098; Clements Bros., $18,149; W. J. Townsend, $18,324; and John Potts Co., $19,721.

Clay Center, Kan.—City Clk. W. K. McAulis writes that it is proposed to construct about 17 blocks of sewers in Dist. No. 1 and 850 ft. of public sewer; main sewers to be 15-in. tiling and laterals of 6 or 8-in. tiling; bids will probably be wanted in about 30 days. Estimated cost about $7,000.

Burlington, Ia.—Bids are wanted Oct. 6 for constructing the North Oak St. sewer and branches. Emmett Steece, City Engr.

Milwaukee, Wis.—It is stated that bids are wanted Sept. 30 for constructing a brick sewer in Delaware Ave. and a pipe sewer in Scott St. Chas. J. Poetsch, Chmn. Bd. Pub. Wks.

Irvington, N. J.—The following bids were opened Sept. 16 for building a sewerage system for this town. Alexander Potter, of New York City, Ch. Engr.:

Items and Quantities.	*Headley & Christie, Newark.	Jas. Conway, Orange, N. J.	David Peoples, Phila., Pa.	Ludwig Batt, S. Orange, N. J.
8-in. pipe sewer, 0—6 ft. deep, 3,370 ft	$.45	$.58	$.63	$.60
8-in. pipe sewer, 6—8 ft. deep, 29,491 ft	.50	.60	.70	.75
8-in. pipe sewer, 8—10 ft. deep, 12,770 ft	.55	.65	.80	1.00
8-in. pipe sewer, 10—12 ft. deep, 4,395 ft	.60	.75	.90	1.15
8-in. pipe sewer, 12—14 ft. deep, 1,570 ft	.65	.85	1.10	1.25
8-in. pipe sewer, 14—16 ft. deep, 770 ft	1.00	.90	1.80	1.35

Totals	$46,021	$57,063	$65,595	$67,491

*Contract awarded.

Washington, D. C.—Supt. of Sewers D. E. McComb writes that the following bids were opened Sept. 13 for the construction of sewers: *a*, Sewer A; *b*, Sewer B; *c*, Sewer C, etc.: Jno. F. Joyce, Washington, *a* $2,055.50, *e* $4,501.90, *f* $2,910.95, *g* $1,455; The Warren F. Breniger Co., Washington, *a* $28,079.60, *b* $9,490.53, *c* $2,035.90, *d* $2,032.20, *e* $3,082.23, *f* $2,282.55, *g* $1,229; M. F. Taity, Washington, *a* $29,936, *b* $9,191.65, *c* $1,621.50, *d* $2,250.50, *e* $3,091; Andrew Gleeson, Washington, *a* $21,360, *b* $12,495.68 *c* $1,974.10, *d* $2,476; Coyle & Co., Washington, *a* $24,591.89, *b* $11,841.75, *c* $2,494, *d* $2,130.65, *e* $2,733.75, *f* $2,424.60, *g* $1,301; Lyons Bros., Brookland, D. C., *a* $28,656.60, *c* $2,008, *d* $2,481, *e* $2,963.24, *f* $2,291.20, *g* $1,264.

Roanoke, Va.—Bids will be received by W. E. Thomas, Clk. of the City Council, until Oct. 3 for furnishing material and constructing sewers in Section 8. J. H. Wingate, City Engr.

Washington, D. C.—The Supt. of Sewers has transmitted to the Commissioners a plan and specification for the construction of a sewerage system at the Industrial Home School.

Cape Charles, Va.—Local press reports state that surveys are about to be made for an improved sewerage system.

Toledo, O.—Bids are wanted Oct. 6 for furnishing material and constructing 24-in. circular brick sewer, with 4-in. shell, in portions of 2 streets; also for furnishing material and constructing 15, 12, 10 and 8-in. circular pipe sewers in portions of several other streets. Chas. H. Nauts, City Clk.

Kansas City, Mo.—Contracts for sewer construction (bids opened Sept. 19) have been awarded as follows: To Mat. Kinlin, Kansas City, Dist. 198, which includes 7,000 ft. of pipe sewer, 18 manholes, 8 catch basins and 5 flushtanks, at a total of $11,469; to R. W. Mullens, Kansas City, Dist. 162, which includes 7,300 ft. of pipe sewer, 28 manholes, 5 catch basins and 5 flushtanks, at a total of $7,342. The lowest bid on Dist. 208, which includes 13,400 ft. of pipe sewer, 2,200 ft. of brick sewer, 55 manholes, 45 catch basins and 7 flushtanks (contract not awarded), was from Michael Walsh at $36,340.

Clinton, Ia.—City Engr. Chas. P. Chase has placed the estimated cost of 5th St. storm water sewer system, comprising about 4 miles of brick and pipe sewer, at $18,500.

Wichita, Kan.—The construction of a storm water sewer system is under consideration.

Jerseyville, Ill.—The City Council has passed a resolution authorizing the construction of a sewerage system.

Two Rivers, Wis.—The contract for constructing a sewerage system is stated to have been awarded to Murphy & Gray, of Manitowoc, for $16,000.

Indianapolis, Ind.—City Engr. Nelson has completed plans for the Bloyd Ave. sewer, which will be a circular drain 3 ft. 9-in. in diameter at the beginning and taper to an 18-in. pipe.

Lake Charles, La.—Press reports state that the City Council has decided to install a complete system of sewerage.

Lexington, Ky.—The General Council has passed an ordinance authorizing the submission to a vote of the people at the Nov. election of the question of issuing $150,000 bonds for the construction of a sanitary sewer system.

Nashville, Tenn.—The City Council has passed bills appropriating $73,000 for the extension of the Eaglefield branch sewer, and $2,200 for extension of Wharf Ave. sewer.

Sherman, Tex.—See "Water."

Little Rock, Ark.—It is stated that bids are wanted by Jas. F. Kieser, Engr. in charge, until Oct. 4 for constructing about 4 miles of 6, 8 and 10-in. pipe sewers.

Douglas, Wyo.—Bids will be received until Oct. 1 by Otto H. Bolln, Town Clk., for constructing a system of sewerage in this town.

Ft. Keogh, Mont.—The contract for constructing a sewer system at this post has been awarded to M. Ilgen & C. Armberg, of Miles City, Mich., for $9,639. Bids were opened Sept. 22 by Ch. Q. M. Geo. E. Pond.

Denver, Colo.—Citizens from Globeville and Elyria have protested to the Bd. of Pub. Wks. against the emptying of the Denver sewer into Platte River near their towns; they ask that the main line be extended at least one mile.

Torreon, Mex.—See "Water."

BRIDGES.

Reading, Pa.—Bids will be received by John F. Ancona, Co. Compt., until Oct. 1 for constructing a bridge in Washington Township.

Scranton, Pa.—Bids will be received by the Co. Comrs. until Sept. 30 for constructing the following bridges: 1 expanded metal concrete arch bridge near D., L. & W. station at La Plume; the following steel girder corrugated iron, concrete floored bridges: 1 in Glenburn Boro. near Waverly line; 1 over Kennedy's Creek in North Abingdon turnpike; and 1 over Whitney's Creek in West Abingdon Township; 1 steel truss bridge over Spring Brook in Spring Brook Township. E. T. Jones, Co. Compt.

Trenton, N. J.—The Berlin Iron Bridge Co., East Berlin, Conn., is reported to have secured the contract to construct a bridge at Olden Ave. for $20,300.

Downingtown, Pa.—It is stated that the Co. Comrs. and the Trolley Co. are considering the building of a bridge across Brandywine Creek, in this city. Walter McDonald, Co. Surv., West Chester, Pa.

New York, N. Y.—Bids are wanted Oct. 2 for taking down and rebuilding the westerly abutment of bridge across the tracks of the N. Y., N. H. & Hartford R. R. at the crossing of the Bronx and Pelham Parkway. Wm. R. Willcox, Comr. of Parks.

Pulaski, Pa.—Y. B. Zohniser, of New Castle; W. P. Davis, of Towanda; Chas. E. Hoke, of Chambersburg, and W. H. Middleton and F. P. Snedgrass, both of Harrisburg, have been appointed as viewers to inquire into the necessity of rebuilding a bridge across Chenango River, at Pulaski.

Philadelphia, Pa.—Local press reports state that according to plans agreed upon by the Rapid Transit Co. and the City authorities, the present piers of the Market St. bridge will be extended on the south and the entire bridge moved several feet toward Chestnut St. The piers on the north will also be extended and strengthened and an elevated structure built on them.

Philadelphia, Pa.—The following bids were opened Sept. 20 by Wm. C. Haddock, Dir. Dept. of Pub. Wks., for the approaches to and piers of proposed bridge over Schuylkill River on the line of Passyunk Ave.: Armstrong & Printzenhoff, $39,390; time 9 months; Hoffman Engineering Co., $36,230; 7 months; David Peoples, $23,927; 6 months; Henderson & Co., Ltd., $49,777; 12 months; McGaw & Gray, $29,266; 5 months.

Bids opened at the same time for the construction of an intercounty bridge over Poquessing Creek on the line of Frankford Road: Henderson & Co., $42,000; time 6 months; McCormick & Co., $34,000; 6 months; David Peoples, $38,000; 6 months.

Boston, Mass.—Bids will be received by the City Engr. until Oct. 8 for steel superstructure of Sections A and B, Broadway Bridge, and giving bond of a Surety Co. in $25,000.

Vickers Ferry, N. Y.—It is stated that bids are wanted by J. R. Strong, Village Pres., until Oct. 1 for constructing a 3-span, 162 ft. long, 16 ft. wide, iron bridge on stone foundation; estimated cost, $35,000. C. E. Hicks, Des. Engr.

Doylestown, Pa.—Local press reports state that the following bids were received by the Co. Comrs. Sept. 20 for constructing an intercounty bridge at the Red Lion Hotel, Torresdale: Henderson & Co., $42,000; David Peoples, $38,000, and McCormick & Co., $34,000.

115 & 117 Cannon St, br stores and tenemt; c, $40,000; o, Hershkovits, Roth & Klein; a, Bernstein & Bernstein.

171 & 173 W 4th St, br stores and flat; c, $30,000; o, Robt Friedman; a, Sass & Smallheiser.

244 & 246 7th St, br stores and flat; c, $40,000; o, Newman & Spielberger; a, Sass & Smallheiser.

Berger Ave & Rose St, br storage & stable; c, $20,000; o, Theo J Chabot; a, Albert Rothermel.

34 E 12th St, extension to br loft bldg; c, $71,700; o, Empire Realty Co; a, G Starrett.

327 and 329 W 108th St, improv to 2 br bldgs; c, $65,000 all; o, Geo W Wilder; a, Hogan & Slattery

251 5th Ave, improv to br stores and flat; c, $80,000; o, Beacon Hill Real Estate Co; a, Bruce Price; b, Chris Campbell.

1 to 13 Hancock St, 3 br stores & flats; c, $105,000; o, Freedman & Feinberg; a, Bernstein & Bernstein.

Hester & Centre Sts, br and terra cotta factory; c, $115,000; o, John L Daniels; a, De Lemos & Cordes.

343½ to 345 Water St, br stores & tement; c $40,000; o, Union Construction & Realty Co; a, Bernstein & Bernstein.

15th and 16th Sts & 9th Ave, br factory; c, $300,000; o, National Biscuit Co; a & b, Louis Weber Bldg Co.

47th St and 8th Ave, br stable; c, $125,000; o, Adams Express Co; a, Bruce Price.

58th St and 8th Ave, br and stone hotel; c, $200,000; a, Jas D Matthews; a, Ross & McNeil.

82 to 88 E 110th St, 2 br stores & tenemts; c, $80,000 all; o, W & J Bachrach; a, Bernstein & Bernstein.

117th St & 5th Ave, br stable; c, $25,000; o, Thos D Malcolm; a, Harry T Howell.

Chambers & Reade Sts and Broadway, vault and doors to 6-story office & bank bldg.; c, $30,000; o, Emigrant Industrial Savings Bank; a, J M Mossman.

Grand & Allen Sts, new store front and alterations to br loft bldg; c, $25,000; o, Goldman & Multzman; a, Bernstein & Bernstein.

DWELLINGS.

Boston, Mass.—Plans have been filed by Herbert C. Britwell, 16 State St., for a block of four 3-story 3-family brick and stone houses on Harvard Ave., Brighton Dist. Estimated cost, $65,000. Owner, Grantham Terrace Trust. Builder, Boston Const. Co. Architect, Benj. Fox, 72 Devonshire St.

Pittsburg, Pa.—Geo. N. Powell is reported as having plans prepared for a 4-story brick apartment house which he intends building on Maryland Ave. and Elmer St., 20th Ward; cost, $42,000.

Cleveland, O.—Harry L. Vail will erect a 4-story apartment building on Euclid and Willson Aves., to cost $50,000. Fenimore C. Bate, New England Bldg., Archt.

St. Louis, Mo.—It is stated that plans are being prepared by Barnett, Haynes & Barnett, 8th and Locust Sts., for an apartment house for W. F. Williamson, to be located on Hamilton and Maple Aves. It will be of red stock brick trimmed with a cream color terra cotta; cost, $125,000.

Logansport, Ind.—An apartment house to cost $25,000 is to be erected by Keller Bros.

Denver, Colo.—Adolph Zang, of the Zang Brewing Co., is reported to be having plans prepared for a dwelling to be erected on 7th Ave. and Clarkson St., to cost between $75,000 and $100,000.

NEW YORK CITY.

Permits for the following buildings have been issued: c, signifies cost; o, owner; a, architect; m. mason; cr, carpenter; and b, builder.

94th St and Riverside Drive, br and stone tenemt; c, $85,000; o, Wm Rankin; a, Hy Anderson.

165th St and Bway, br tenemt; c, $22,000; o, John A Picken; a, John Hauser.

5th Ave & 79th St, br dwelg; c, $125,000; o, J C Lyons; a, McKim, Mead & White.

160th St, Amsterdam and St Nicholas Aves, br and stone flat; c $70,000; o & a, Streifler Bros.

308 5th Ave, extension and improv to br and stone dwelg; c, $20,000; o, Jaques Krakauer; a, Buchman & Fox.

SCHOOLS.

New York, N. Y.—Bids are wanted Oct. 3 for alterations in School No. 70. C. B. J. Snyder, Supt. of School Bldgs., Dept. of Educ.

Brooklyn, N. Y.—Bids will be received until Oct. 3 by C. B. J. Snyder, Supt. of School Bldgs., Dept. of Educ., N. Y. City, for sanitary work in School No. 139 and for installing heating apparatus and electric lighting plant for Manual Training School Annex, Nos. 75 and 79, Boro. of Brooklyn.

Gloversville, N. Y.—Bids will be received by the Bd. of Educ. until Oct. 4 for erecting a brick school in the 6th Ward. C. S. Schermerhorn, Chmn. Bldg. Com.

Rochester, N. Y.—J. C. Sterns & Co., of Buffalo, are stated to have secured the contract for wiring the new east side high school for $4,970.

Woodbridge, N. J.—The Bd. of Educ. is stated to have decided to build 2 schools. One will be an 8-room addition to School No. 1. The other will have 12 rooms, and it will be located at Carteret.

South Orange, N. J.—Kellogg & Co., New York, N. Y., are stated to have secured the contract for ventilating and heating the 2 proposed new schools for about $6,000.

Buffalo, N. Y.—The Sisters of the Good Shepherd will erect a $17,000 addition to the convent at 485 Best St.

Westfield, Mass.—W. D. Mellen, 111 Dwight St., Springfield, is stated to have secured the contract for erecting a dormitory for the State Normal School; probable cost, $50,000.

Sylvester, Ga.—Bids are wanted Oct. 1 for erecting a $10,000 brick school. W. E. Grubbs, Town Clk.

Athens, O.—Bids will be received by the Bd. of Trus. of the Ohio Univ. at Athens until Oct. 7 for furnishing material and erecting the main portion of the Normal School at the Univ. L. M. Jewett, Secy.; Frank L. Packard, Archt., New Hayden Bldg., Columbus.

Chicago, Ill.—It is stated that a $40,000 school is to be erected for St. Alphonsus R. C. Church. Architect, Henry P. Beiler, 84 La Salle St.

Murphy & Camp, 632 N. Wells St., are stated to have prepared plans for a parochial school to be erected at N. Ashland and Leland Aves. for Our Lady of Lourdes R. C. Church. It will be 3 stories high, 60x122 ft., of pressed brick and stone, and cost about $50,000.

Warsaw, Ill.—The plans of W. H. Reeves, of Peoria, are stated to have been accepted for an 8-room school, to cost about $19,000.

Halstad, Minn.—Bids will be received by the Bd. of Educ. until Oct. 18 for $14,000 school bonds. H. P. Nygaard, Clk.

Milwaukee, Wis.—Competitive plans and specifications will be received until Oct. 24 by the Bd. of Pub. Wks. for a school to be erected on 5th and 6th Aves, in the 14th Ward, and for a school to be erected on Cass St., 1st Ward. Chas. J. Poetsch, Chmn.

Mobile, Ala.—The Superintendent's report to the Comrs. recommends the appropriation of $30,000 for improvements on present school building.

Greeley, Colo.—The contract for the superstructure of the State Normal School is stated to have been awarded to Knutson & Isdell for about $23,000.

STREET CLEANING AND GARBAGE DISPOSAL.

Meadville, Pa.—City Engr. W. A. Doane writes that bids are wanted Oct. 1 for the construction of a 25-ton garbage furnace. Probable cost, $10,000.

Evansville, Ind.—Bids will be received by the Bd. of Pub. Wks. until Oct. 4 for sweeping and cleaning certain streets in the city for 1 year. W. Edw. Clarke, Clk.

Grand Marias, Mich.—This village is said to be about to purchase a garbage disposal plant.

Kansas City, Mo.—Council Committees are considering with City Physician Langsdale the question of disposing of city garbage.

Chicago, Ill.—The City Council has appropriated $50,000 for additional street cleaning.

Mobile, Ala.—The Bd. of Pub. Wks. has received a proposition from Gerald H. Kruempel, offering to clean the 17,000 yds. of asphalt now laid, each morning, for the sum of one cent per yd. per day.

Oakland, Cal.—The Bd. of Health has passed a resolution urging the Council to adopt at an early date a permanent means for the disposal of garbage.

GOVERNMENT WORK.

Portland, Me.—The following bids were opened Sept. 22 by Maj. S. W. Roessler, Corps of Engrs., U. S. A., for dredging in Lubec Channel, Me.: *a*, price per cu. yd. scow measure for about 200,000 cu. yds. of dredging; *b*, price per ton for boulders: Eastern Dredging Co., Portland, Me., *a* 24¾ cts., *b* $5; Morris & Cummings Dredging Co., New York, N. Y., *a* 26½ cts., *b* $8.

Pittsburg, Pa.—Bids were opened Sept. 18 by Capt. Wm. L. Sibert, Corps of Engrs. U. S. A., for the construction of a lock keeper's house and office at the Herr's Island dam, and the lowest bid is stated to have been from Martsolf Bros. at $6,800.

Philadelphia, Pa.—Bids will be received until Oct. 11 by Mordecai T. Endicott, Ch. Bureau of Yards & Docks, Navy Dept., Washington, D. C., for constructing a sheet steel house for locomotive crane machinery, at the Navy Yard, League Island, Pa. Bids will also be received at the same Department until Oct. 18 for constructing a steel and brick building for a foundry and coppersmith shop for steam engineering at the Navy Yard, League Island, Pa.

Philadelphia, Pa.—Bids will be received until Sept. 30 by the Bureau of Supplies & Accounts, Navy Dept., Washington, D. C., for furnishing at the Navy Yard, League Island Pa., a quantity of railroad material, foundry cupola, blowers, hand crane, travelling crane, machine tools, etc. A. S. Kenny, Paymaster-Gen., U. S. Navy.

Boston, Mass.—Bids will be received until Oct. 18 by Mordecai T. Endicott, Ch. Bureau of Yards & Docks, Navy Dept., Washington, D. C., for dredging at the Navy Yard, Boston. Estimated cost, $22,500. Bids will also be received at the same Dept. until Oct. 18 for constructing a pile and timber wharf at the Navy Yard, Boston; estimated to cost $2,900.

Washington, D. C.—Bids are wanted Oct. 9 for safety vaults and work incidental thereto, in the Bureau of Engraving and Printing, U. S. Treas. Dept., Washington, D. C. Jas. Knox Taylor, Superv. Archt., Treas. Dept.

Tampa, Fla.—Local press reports state that the following bids were opened Sept. 15 by Capt. Herbert Deakyne, Corps of Engrs., U. S. A., for improving the channel from Hillsboro River to the deep water in Tampa Bay; the work includes 18,000 cu. yds. of rock and 370,000 yds. of earth to be removed; amount available, $150,000; National Dredging Co., of Wilmington, Del., offered to remove the rock for $112,000, and the dredging for $97,125; total, $209,625. Edwin W. Preston, of this city, offered to do the work for $157,857.

Annapolis, Md.—Press reports state that bids opened Sept. 19 at the Navy Dept., Washington, D. C., for the erection of 6 double houses and one single house, to be used as officers' quarters, were rejected, being in excess of the appropriation, which is $285,000.

Cleveland, O.—The following bids were opened Sept. 18 by Maj. Dan C. Kingman, Corps of Engrs., U. S. A., for constructing and repairing piers at Fairport Harbor: *a*, total bids if oak is to be used; *b*, total bid if other acceptable hardwood is to be used: A, W. C. Gayer, Cleveland, O., *a* $154,230, *b* $153,480; B, Donnelly Contracting Co., Buffalo, N. Y., *a* $135,881, *b* $133,911; C, L. P. & J. A. Smith Co., Cleveland, O., *a* $160,507, *b* $160,507. For detail bids see accompanying table:

Items and Quantities.	A	B	C
East pier reconstruction:			
Rem. old pier, 7,500 cu. yds.	$1.00	$.50	$1.50
Dredging, 15,000 cu. yds.	.40	.25	.40
Hemlock timber, 640 M. ft.	28.00	28.50	28.00
Old timber decking, etc., 22 M. ft.	10.00	22.50	20.00
Oak timber, 65 M. ft.	60.00	46.25	50.00
*Timber, 65 M. ft.	55.00	36.00	50.00
Tie rods and washers	.06	.04	.06
Drift bolts	.06	.04	.05
Screw bolts, etc, 180,000 lbs.	.06	.04	.06
Lag screws and washers	.06	.04	.06
Spikes	.06	.04	.05
Concrete blocks, 710 cu. yds.	14.00	11.37	15.00
Concrete in mass, 2,100 cu. yds.	8.00	7.50	8.00
Small riprap stone filling, 10,500 tons	1.50	1.33	1.60
West pier reconstruction:			
Rem. of old pier, 3,500 cu. yds.	1.00	1.00	1.50
Other excav., 1,800 cu. yds.	.40	.25	.30
Sheet piling, 170 M. ft.	55.00	50.00	50.00
Old timber decking and found., 25 M. ft.	10.00	27.50	30.00
Oak timber, 7 M. ft.	50.00	56.25	50.00
*Timber, 7 M. ft.	50.00	46.00	50.00
Hardwood piles in place, 17,500 lin. ft.	.35	.35	.35
Pile rings and shoes, 10,000 lbs.	.10	.075	.10
Tie rods and washers	.06	.04	.06
Drift bolts	.06	.04	.05
Screw bolts, etc., 50,000 lbs.	.06	.04	.06
Lag screws and washers	.06	.04	.06
Spikes	.06	.04	.06
Refilling pier and backfill. with stone from old cribs, 2,000 cu. yds.	1.50	1.31	1.60
Backfill. with sand, 1,500 cu. yds.	1.00	.44	.50
Concrete blocks, 575 cu. yds.	14.00	11.25	15.00
Concrete in mass, 1,200 cu. yds.	8.00	7.50	8.00
Sawed sandstone flagg., 6-in., 3,800 sq. ft.	.40	.44	.40
Sheathing and repairing old piers:			
3-in. white oak plank, 85 M. ft.	120.00	137.50	120.00
*3-in. plank, 85 M. ft.	115.00	123.00	120.00
Lag screws, etc., 30,000 lbs.	.06	.04	.06
Pine plank, 85 M. ft.	35.00	44.00	40.00
Pine stringers, 12 M. ft.	35.00	44.00	40.00
Hemlock timber, 30 M. ft.	28.00	29.00	30.00
Drift bolts	.06	.04	.05
Screw bolts, etc., 20,000 lbs.	.06	.04	.06
Spikes	.06	.04	.05

*Beech or other acceptable hardwood.

Chicago, Ill.—The following bids were opened Sept. 18 by Lieut.-Col. O. H. Ernst, U. S. Engr. Office, for constructing breakwater at Calumet Harbor: Gillen & Gillen, Racine, Wis., $278,939; The FitzSimons & Connell Co., Chicago, Ill., $295,636; T. J. Bennett & Co., Muskegon, Mich., $293,431; Lydon & Drews Co., Chicago Ill., $315,686; McArthur Bros. Co., Chicago, Ill., $330,475; Hausler & Lutz Towing & Dock Co., Chicago, Ill., $279,685.

Chicago, Ill.—The following bids (with dates of completion) were opened Sept. 21 at the Treasury Dept., Washington, D. C., for the interior finish and completion of the Post Office, Court House, etc., Chicago, including carpentry, fireproofing, glazing, marble, ornamented iron, painting, plastering, etc. (but not including plumbing and mechanical plants): John Peirce, N. Y. City, $1,478,500, Jan. 1, 1905; Wm. Grace Co., Chicago, $1,895,000, Sept. 1, 1904; Davidson Bros. Marble Co., $1,895,000, 27 months; Congress Const Co., $2,181,151, July 1, 1905; John Griffiths & Son, $1,930,000, Nov. 15, 1904.

Ft. Riley, Kan.—Capt. G. O. Cress, Constructing Q. M., writes that contracts for the construction of buildings, etc., at this post (bids opened Aug. 25) have been awarded as follows:

Construction proper: To Ziegler & Dalton, Junction City, Kan., 3 field officers' quarters, $39,255, and 2 double line officers' quarters, $39,800; to Moses & Holmgren, Junction City, Kan., 1 artillery barracks, $44,850, and 1 bakery, $15,900; to Jos. B. Betts, Topeka, Kan., 1 double cavalry barracks, $39,984; 1 gun shed, $21,300; 1 artillery stable, $21,600, and 1 cavalry stable, $18,600.

Plumbing and heating: To J. J. Hanighen, Omaha, Neb., *a*, plumbing; *b*, heating: double cavalry barracks, *a* $5,881, *b* $4,109; artillery barracks, *a* $3,872, *b* $3,327; gun shed, *a* $512; artillery stable, *a* $694; cavalry stable, *a* $675; field officers' quarters, *a* $2,067, *b* $2,000; double line officers' quarters, *a* $2,815, *b* $2,470; bakery, *a* $717, *b* $678.

Electric wiring several of the buildings to Riddle & Landon, St. Paul, Minn., at a total of $2,866.

Breadmaking machinery to Jas. Foley, Leavenworth, Kan., for $1,644.

Bids for the construction proper of 2 non-commissioned staff quarters being considered excessive, same were rejected, and these buildings will be readvertised for similar structures, but to be of brick instead of stone.

Des Moines, Ia.—Contracts for work at Ft. Des Moines (bids opened Aug. 25) are stated to have been awarded as follows: Construction—S. A. Robertson, of Des Moines, 3 buildings, $64,474; R. P. and Edw. O. Hamilton, Omaha, 15 buildings, $177,391.

Plumbing—L. H. Kurtz, Des Moines, 4 buildings, $3,612; Dwyer Heating & Plumbing Co., of St. Paul, 5 buildings, $12,812; H. C. Clark, Delaware City, 5 buildings, $2,681.

Steam and hot water heating—Harris & Algor, Camden, N. J., 8 buildings, $14,722.

Gas piping—Dwyer Plumbing & Heating Co., 10 buildings, $990.

Electric wiring—Riddle & Landon, St. Paul, 11 buildings, $2,845.

New Orleans, La.—The following bids were opened Sept. 8 by Lieut.-Col. Henry M. Adams, Corps of Engrs., U. S. A., for extension to and repairs to jetties at Calcasieu Pass, La., and Sabine Pass Harbor, Tex. *Contract awarded:

Bidders and Addresses.	Mattress, Est. 7,000 sq. yds.	Riprap stone, Est. 79,000 net tons.	Replacing granite blocks, Est. No. of 200 per blocs	Total.
John Short, St. Louis, Mo.	$.95	$2.50	$1.50	*$204,450
O. M. Stone, Sabine, Tex.	1.40	3.10	9.50	256,600

Bids opened Sept. 2 by Lieut.-Col. Henry M. Adams, Corps of Engrs., U. S. A., for dredging at Calcasieu Lake, La., and Sabine Pass, Tex., were as follows:

Items and Quantities.	Bowers Southern Dredg. Co. Galveston, Tex.	Atlantic, Gulf & Pacific Co., N. Y.
Sabine, 187,500 cu. yds., per cu. yd.	$.225	$.260
Calcasieu, 55,000 cu. yds., per day of 16 hours	400,000	600,000
Total Sabine Pass (approximate)	$41,250	$48,750
Total Calcasieu Lake (approximate).	$9,000	$9,000

The following bid was opened Sept. 22 by Lieut.-Col. H. M. Adams, Corps of Engrs., U. S. A., for dredging at Chefuncte and Amite Rivers, La.: Jahncke Navigation Improv. Co., New Orleans, 35,000 cu. yds. at 17½ cts. per cu. yd.; total, $6,125.

Dover, Tenn.—Bids are wanted Oct. 14 for constructing a roadway to National Cemetery at Dover. C. D. V. Hunt, Q. M., New Orleans, La.

Memphis, Tenn.—Press reports state that bids will be received until Oct. 2 by Capt. E. E. Winslow, Corps. Engrs., U. S. A., for levee enlargement in the 3d Dist. of the Mississippi River, which will involve about 315 cu. yds. of earth work.

Bremerton, Wash.—Bids will be received until Oct. 25 by Mordecai T. Endicott, Ch. Bureau of Docks and Yards, Navy Dept., Washington, D. C., for constructing an extension of the concrete wing wall, Navy Yard, Bremerton. Estimated cost, $16,000.

San Francisco, Cal.—Bids will be received until Oct. 16 by the California Debris Comn., Flood Bldg., San Francisco, for building portions of dam (known as Barrier No. 1) on Yuba River, Yuba Co., about 14 miles above Marysville, Cal. Address Lieut. R. P. Johnston, Corps Engrs., U. S. A.

Bids are wanted Oct. 20 for removing Blossom Rock, San Francisco Harbor, Cal., to a depth of 30 ft. below low water. Address Lieut.-Col. W. H. Heuer, Corps Engrs., U. S. A., San Francisco.

Sheridan, Wyo.—Bids are wanted Oct. 15 for constructing, plumbing, heating, gas piping and electric wiring 2 double sets officers' quarters, 1 double barrack and 1 bakery, all brick. Address Quartermaster.

San Francisco, Cal.—Bids are wanted Oct. 15 for constructing a brick fog-signal building, brick chimney and erection of boilers at Bonita Point Light Station, Cal. Lieut.-Col. Thos. H. Handbury, Corps Engrs., U. S. A., Light House Engr.

MISCELLANEOUS.

Boston, Mass.—Bids will be received until Oct. 9 by the Bd. of Harbor & Land Comrs. for dredging in Dorchester Bay; work to be done includes about 395,000 cu. yds. of material to be dredged from 2 areas in Dorchester Bay near City Point, Boston Harbor. Woodward Emery, Chmn.

New York, N. Y.—Bids are wanted Oct. 7 for furnishing material and building a pier with appurtenances on the westerly side of North Brother Island, Boro. of Bronx. McDougall Hawkes, Comr. of Docks, Dept. of Docks & Ferries.

Jersey City, N. J.—Ch. Engr. Van Keuren has prepared a map for the improvement, to cost about $8,000, of the property acquired for the enlargement of Columbia Park, and has been asked to prepare plans for the improvement of the new portion of River View Park; estimated cost about $20,000.

Boston, Mass.—The Mayor has signed the $25,000 loan order for park construction.

Duluth, Minn.—Local press reports state that the Duluth Dock & Dredge Co. has decided to build a new $125,000 dredge.

Escanaba, Mich.—The contract for foundation for the $1,000,000 ore docks to be built at Escanaba by the Chicago & North Western Road is stated to have been awarded to Whitney Bros., of Duluth, for $50,000.

Portland, Ore.—Engrs. Huber & Maxwell estimate the cost of preparing the selected site for the 1905 Fair, at $24,095.

Toronto, Ont.—The Bd. of Control has authorized the expenditure of $18,000 for the new cribwork at the foot of Bay St.

NEW INDUSTRIAL PLANTS.

Warlick & Whisnant, Granite Falls, N. C., are in the market for a 35 to 40-H.-P. boiler, a 25 to 30-H.-P. engine and wood-working and excelsior machinery.

The Lansing, Mich., Wheelbarrow Co. is building a 60x200-ft. addition for making steel scrapers.

The Burton D Hurd Co., Temple Block, Kansas City, Mo., will erect a 4-story, 50x70-ft. rice mill, having a daily capacity of about 1,200 bbls.; a 2-story, 100x122-ft. warehouse for rough rice, and a 2-story, 50x122-ft. warehouse for clean rice.

The Knott & Van Arnam Mfg. Co., Coldwater, Mich., makers of plumbing specialties, will erect a 50x200-ft. factory, with boiler house and dry kiln, at Fort Wayne, Ind. The capacity of the power plant will be about 100 H.-P.

The Merchants' Refrigerating Co., Kansas City, Mo., has been incorporated to erect a 5-story cold storage plant having a capacity of about 400 carloads. It is also proposed to operate a street pipe line for furnishing refrigeration. J. E. Brady, 407-11 Grand Ave., is interested.

The Atlas Co., Lincoln, N. J., miners and refiners, are adding a dry house and mechanical dryer to their plant at that place, and erecting mill buildings, 50x125 and 50x175 ft., respectively, at Mertztown, Pa., to have a power plant of about 250 H.-P.

Winfield Scott and M. E. Singleton, of Fort Worth, Tex., will be president and general manager, respectively, of a company which expects to build a cottonseed-oil mill at East St. Louis, Ill., having a daily capacity of 150 tons of seed. The company will not be ready to take up the question of machinery until about Jan. 1.

Max Lowenthal & Bro., 428-438 Main St. E., Rochester, N. Y., will erect a 3-story and basement knitting mill to have about 50,000 sq. ft. floor space. The plant will be run by electricity, and the company is in the market for motors and 60 to 80 H.-P. in boilers for heating.

The Ardmore, I. T., Coal & Power Co. is putting in a brick plant to have a daily capacity of 44,000 bricks. After the brick plant is running, a tile and pottery plant will be put in.

The Hubbard Fertilizer Co., Baltimore, Md., will soon be in the market for a complete outfit for a new plant to replace that recently burned.

The Barberton, O., Pottery Co. will build an addition, which will include several new kilns and extensive buildings.

The Marshalltown, Ia., Pottery Co. is in the market for a 75-H.-P. engine for a 4-kiln plant it proposes to erect.

The J. T. Deloach Lumber Co., Ltd., State Line, La., expects to build a mill at Homer, La., which will have a daily output of 40,000 to 50,000 ft. It is intended to install a steel tram road to handle logs.

The Virgor-O Health Food Co., Ltd., Owosso, Mich., mentioned last week, has secured a site for its factory, and is now ready to take up the matter of machinery, including engines.

BUSINESS NOTES.

The Ball Engine Co., Erie, Pa., reports the following among its recent orders: Loveland, Colo., Beet Sugar Co., an engine direct-connected to a Crocker-Wheeler generator; Armour Elevator, New Orleans, an engine direct-connected to a Triumph generator; Evans, Almirall & Co., two engines direct-connected to centrifugal pumps, for the new shops of E. P. Allis & Co., Milwaukee.

The New England Structural Co., of Boston, has just shipped the steel framework for the Minneapolis General Electric Company's power station. The material was shipped complete in two weeks from receipt of the order.

The Baltimore Bridge Co., recently organized, has purchased the entire business of the Structural Iron & Steel Co., of Baltimore, Md. The plant has recently been completely remodeled, and is capable of turning out 7,000 tons annually of bridge and structural work: all tools and machinery being of the most modern character and driven by either electric or pneumatic power. Plans are now under way to more than double the capacity of the plant by the addition of a girder shop capable of turning out the heaviest type of reamed and solid-drilled work. Nathaniel Haven, Pres.; Alfred M. Mosscrop, Vice-Pres. and Mgr.

The Philadelphia Pneumatic Tool Co. reports that in the month of August it broke all previous records in the amount of goods shipped. Recent large orders have been received from the Cambria Steel Co., Pennsylvania Steel Co., New York Shipbuilding Co., Newport News Shipbuilding & Dry Dock Co. and Grand Trunk Ry. Co. Foreign orders have been received from Paris, London and Copenhagen. More orders have come in for rotary drills during the past two months than ever before. The company has just added to its machine shop equipment eight engine lathes, two automatic machines, two turret lathes, two grinding machines, one Fellows gear shaper, six drill presses, one universal milling machine, one twist drill grinder and a number of other minor machine tools.

THE ENGINEERING RECORD.

Volume XLVI., Number 14.

TABLE OF LEADING ARTICLES.

Unreasonable Contract Requirements by the Government.—III. 313
The New Power Plant for the Assabet Mills, Maynard, Mass. (Illustrated).... 314
Submerged Pipe.... 317
A Concrete Power Dam at Middle Falls, N. Y. (Illustrated) 318
Sewage Disposal Works at Nuneaton, England.. 319
The Strength of Concrete-Steel.... 320
The Philadelphia Company's Building, Pittsburg. (Illustrated) 320
The Central States Water-Works Association Convention 323
The New Westinghouse Foundry at Trafford City, Pa. (Illustrated).... 324
Plumbing in the Flat-Iron Building, New York. (Illustrated) 326
Tests of the Glasgow Tramway Engines.... 328

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

Unreasonable Contract Requirements by the Government.—III.

The technical details of engineering specifications should be sufficiently full and explicit to secure beyond question the desired quality of both material and workmanship, but more than that is not only redundant but almost certain to be seriously prejudicial. It is rare that superfluous matter can be introduced into specifications without carrying with it conflicting conditions and, what is worse, requirements not capable of being met or positively injurious if enforced. The Charleston Dry Dock specifications in regard to the Portland cement to be used impress a careful reader as belonging preeminently to this class. Paragraph 53 states "All cement used shall be of the best quality, of an established brand of Portland cement which has been made by the same mill and satisfactorily used in important structures under similar climatic conditions and in sea water for a period of not less than three years. It must be finely ground and free from lumps." Probably few civil engineers would care to compress cement specifications into the limits of a single short paragraph, but any cement fulfilling the requirements of that quoted would be eminently well adapted to the dry dock work at Charleston. The Bureau of Yards and Docks, however, as if distrusting such a concise and well-defined prescription proceeds to impose an extended and elaborate set of exactions, some of which are matters of indifference, some of doubtful value, some harmful and some harmless, but nearly all of them thoroughly superfluous.

A requirement that "All cement shall be of uniform bluish-gray color," strictly speaking, means essentially nothing as to exact color determination, but it would have little or no value if it did. The specifications as to chemical constitution is one of little wisdom in a general application. It is doubtless well enough to express one or two limits in an approximate way as affecting durability in sea water, yet even that is of questionable value except when employed in a reasonable manner, and with the qualifying element of good judgment. What is needed is a cement possessing durability in sea water and if, as prescribed in another paragraph, a given brand has satisfactorily withstood the action of sea water for at least three years that is as near the proof of its capacity as a chemical analysis at this time without comparison with any other.

Paragraph 58 specifies that "No cement shall be used that contains more than 2 per cent. of magnesia, unless positive and satisfactory evidence is furnished that a larger per cent. is not detrimental to the brand of cement used, in which case the amount shall not exceed 3 per cent." If it is conclusively shown that "a larger per cent." than two "is not detrimental," it is natural to inquire why the limit should be three. Again paragraph 59 states "Cement containing an excess of free lime shall not be used," but "an excess" is not defined.

There are other paragraphs in abundance similar in nature to those named and equally indicative of the weak if not worse character of these cement specifications. The checking and cracking tests render superfluous some of the chemical requirements and there are others either aimless or overlapping. The boiling of cement pats in sea water for twenty-four hours is worthless torture, whereas a well-considered accelerated test is sound and reasonable.

The requirements of paragraphs 78 and 79 that in the making of concrete the cement shall be measured "packed in the original package," is a straining after some advantage, apparently, not plainly evident. It might easily result in distinct inconvenience and constitute a marked disadvantage to the progress of the work. It is one of those things which without good sense and judgment based on experience may easily result prejudicially and in no event can result in any real advantage.

The manner of taking samples of cement for testing is "from the interior of bags or barrels." It is not an infrequent experience after exposure of barrels or bags of cement to find the material at and near the exterior of the package partially set from the surrounding moisture while the interior is in perfect condition. The manner of taking the sample prescribed would completely defeat its purpose by avoiding the injured material.

Much of the specifications for making and depositing the concrete is perhaps well enough, but there are other provisions so erratic that one is forced to the thought that scissors and paste rather than experience and judgment have been the ruling instrumentalities in the preparation of these specifications. In paragraph 81 the instructions for depositing concrete in layers so that the top of each shall be a horizontal plane, are such as to induce to the greatest possible extent the lamination of the material. Again in paragraph 83 there occurs the sentence "Concrete shall be tamped at the rate of not more than 72 square feet of concrete 9 inches thick per man per hour." The same paragraph further prescribes that the number of blows and height of fall are to be regulated by the civil engineer in charge. Any such minute and finical regulation in connection with the tamping of concrete is whimsical and ridiculous. If concrete is laid in such condition as to require tamping the latter operation should be so conducted as to accomplish the desired purpose, and that result is the only rational limit of the number and height of blows. Any arbitrary regulation which requires a nice apportionment of the number of blows "per man per hour" without regard to results is calculated to do more harm than good, especially when it is prescribed that such a requirement "shall be rigidly adhered to."

That part of the specifications devoted to the pile work presents features of the same general unsatisfactory class. The following sentences occur in paragraph 95: "The hammer used on the work shall weigh not less than 3,000 pounds nor more than 4,000 pounds. A steam hammer may be used by the contractor if he so desires, but in such event only such dimensions, weight and construction shall be used as shall meet with the approval of the civil engineer in charge." These provisions are apparently based upon lack of experience and unfamiliarity with the class of work to which they apply. Some of the most effective pile driving ever done around New York City, certainly, has been accomplished with a hammer weighing 4,500 pounds and materially heavier hammers have been employed with excellent results. Indeed as a general principle the heaviest hammers including those of the steam hammer class with small falls do much better work in every way than lighter hammers with high falls.

Another characteristic feature of these specifications will be found in paragraph 133 in the following language: "Whatever design be employed the entire responsibility for the sufficiency for the cofferdam shall rest upon the contractor, but the right is reserved to the Government to require that it be perfected in any respect considered necessary by the civil engineer in charge." In other words, under the plea of perfecting it the civil engineer in charge may modify the plan of the cofferdam to any extent whatever, but the contractor must bear all the consequences.

Other citations might be made, but enough has been shown to demonstrate conclusively the absolute unfitness of these specifications for such a great work as the Charleston Dry Dock. They are unworthy of a competent engineering administration of the Bureau of Yards and Docks, and they are not creditable to the Navy Department. They should be recalled, radically recast and put in such shape as to gain to the Government an opportunity to secure the performance of the work on an efficient and businesslike basis.

EXTRACTS FROM SPECIFICATIONS REFERRED TO ABOVE.

38. Tests of Ground.—After the excavation has been completed, the bearing power of the material at the bottom of the same shall be ascertained by tests made by the contractor at his own expense. Not more than five tests will be required under this provision. The location for same will be fixed by the civil engineer in charge. The area loaded for any one test shall be not less than 3 feet square. The method of making the tests shall be as required by the civil engineer in charge, and, if directed, the ground shall be loaded up to 12 tons per square foot. In addition to the above tests in the dry dock proper, the contractor shall, at his own expense, drive in positions shown on plans four test piles, 70 feet long, of the quality and diameter specified in paragraphs 93 and 94, with a hammer weighing not less than 3,000 pounds nor more than 4,000 pounds. During the driving of each test pile the contractor shall afford the Government every facility for keeping a complete and accurate record of the fall of hammer and penetration for each blow. In addition to the above driving tests, the piles shall each be fitted with a platform, and three days after being driven a test load of pig iron, or equivalent, not exceeding 40 tons, shall be applied as may be required by the civil engineer in charge, and facilities shall be afforded for keeping a record of levels during the application of the test load. The test piles shall be left in position and will constitute a portion of the permanent structures. If the tests show that piles will be necessary in the dry dock proper, any test in connection with such test piles will be paid for by the Government, as resulting from a change in contract.

78. Mortar.—All mortar used shall be made with Portland cement, measured packed in the original package, and in the proportions elsewhere specified herein. The volume of cement shall be taken to be that actually filled by the cement itself upon delivery, and shall be ascertained by careful measurement. The sand and cement shall first be thoroughly mixed dry so that when cut down with a shovel the mixture shall show a uniform color without streaks. Water shall then be added slowly, in the form of spray, and the entire mass worked with shovels and hoes to a uniform plastic condition. When thoroughly mixed, very little mortar should adhere to the steel when the hoe is drawn out of it. Only such quantity of mortar as can be used before it begins to set shall be mixed at one time. Sand and cement shall not be mixed dry and allowed to remain for any considerable time before being used.

79. Proportions of Concrete.—Concrete shall be of the following proportions, used in locations specified hereinafter:

	Cement.	Sand.	B'k'n Stone.
Class 1.........	1 part	3 parts	6 parts
Class 2.........	1 part	2 parts	4 parts
Class 3.........	1 part	1 part	2 parts*

*Finely crushed granite.

All shall be by measure. The cement shall be measured packed in the original package, and the actual volume occupied shall be ascertained by careful measurement. Sand and broken stone or gravel shall not be measured in the small wheelbarrows, as is sometimes done, but it will be permissible to use large square wheelbarrows which are of a uniform size and can be filled with a uniform quantity each time. Barrels without heads and boxes without tops and bottoms may also be used; these to be filled only level full with the material to be measured, after which they shall be lifted away. In the side walls of the dry dock structure proper and in the approaches, hard, sound granite blocks or boulders, not exceeding 3 feet in largest dimension, may be embedded in concrete as directed by the civil engineer in charge. No block shall be placed within 2 feet of the limits of the 1 to 3 to 6 concrete or within 1 foot of another one or within 10 feet of the vertical plane of the inner face of the lowest altar of the dry dock. Special care must be taken to entirely surround all such blocks with ½ inch of 1 to 3 mortar so there shall be no voids, and so as to secure a proper bond with the concrete. No boulders shall be placed in the concrete forming the floor of dry dock.

81. Depositing Concrete.—Before any concrete is laid in a trench, or on the site of any foundation, all mud, slush, soft ground, etc., must be removed and refilled with suitable material until a satisfactory bearing is obtained, without extra compensation. Concrete shall be dumped as closely as possible to the place required, so as to avoid, in as great a degree as is practicable, handling or turning it over within the excavation or forms. Concrete shall be deposited in place in homogeneous layers not exceeding 9 inches in thickness. It is not required that one layer be completed before the succeeding layer is started, but layers may be carried along one after the other as closely as practicable consistent with good work as decided by the civil engineer in charge, subject to other requirements of this specification. Where it is impracticable to entirely complete one layer before a second one is started, a plank 9 or more inches in width shall be securely fastened, against which the end of the layer of concrete shall be rammed, thereby securing a vertical joint in this layer. If a second layer has to be stopped before the full length of the work is reached, another cross plank shall be securely fastened at least 3 feet back from the end of the first layer, as shown on sheet 7, and the concrete shall be rammed against it. Layers of concrete must not be tapered off in wedge-shaped slopes, but shall have vertical ends by being built by the above described process. The surface of each projecting layer shall be finished hard and regular, leaving no cavities or loose stones. Layers of concrete shall be kept truly horizontal, and if it is necessary to stop work for an indefinite time the top of the concrete shall be properly finished so that it is a horizontal plane. No concrete shall, under any circumstances, be deposited in place after it has commenced to set, nor shall it be mixed with succeeding batches. When in place and rammed all disturbances must be prevented until at least twelve hours have elapsed. No wheeling or heavy work shall be carried on upon any concrete without first laying down planks for the protection of the concrete. The surface of all concrete masonry shall be kept thoroughly moistened for at least three days after being deposited, and shall be protected in the summer from the direct rays of the sun for a like period. No concrete shall be deposited except by special permission of the civil engineer in charge in writing, during freezing weather or at such times that it is likely to be subjected to freezing within forty-eight hours after being deposited; and then depositing shall proceed only under such conditions and with such precautions as may be directed by the civil engineer in charge. If concrete is likely to be subjected to freezing before it has been allowed to set for forty-eight hours, proper care shall be taken to protect it from the action of frost. The surface of each layer shall be thoroughly moistened before the succeeding layer is deposited upon it, and if it has been exposed more than twelve hours it must be covered with a layer of neat cement ¼ of an inch thick after moistening. The concrete adjacent to the granite facing shall be deposited and tamped in place so as to bond the stone securely to the mass of concrete backing, to the entire satisfaction of the civil engineer in charge. The granite blocks shall first be thoroughly moistened and covered with ¼ inch of 1 to 2, 1 to 1 cement mortar, or neat cement paste, according to the material required for the joints in masonry contiguous to same, in order to obtain a thorough bond between granite and concrete.

83. Tamping Concrete.—The proper tamping of concrete is a matter that shall be given careful attention in order to secure the greatest strength possible, and the requirements stated herein shall be rigidly adhered to. As specified hereinbefore, the amount of water used in mixing concrete shall be such as will permit of tamping being carried on for the period hereinafter specified before a film of water appears on the surface and before concrete begins to quake. Concrete shall be tamped at the rate of not more than 72 square feet of concrete 9 inches thick per man per hour. The number of blows and height of fall shall be regulated by the civil engineer in charge. Each batch shall be thoroughly spread and tamped before another is dumped. Rammers shall weigh not less than 30 pounds, with bases having an area of about 36 square inches.

95. Penetration of Piles.—All piles shall be driven full length, if it is possible to do so without injury, unless otherwise directed by the civil engineer in charge. It is intended that the maximum load per pile shall be 15 tons. The minimum satisfactory length of all piles shall be such as will permit the driving of same to proceed until the average penetration per blow for the last five blows shall not exceed 1½ inches with a 3,000-pound hammer falling freely 20 feet, or the equivalent, unless a modification is authorized by the Chief of the Bureau of Yards and Docks after the excavation has been completed and tests made, as specified in paragraph 38. The hammer used on the work shall weigh not less than 3,000 pounds nor more than 4,000 pounds. A steam hammer may be used by the contractor, if he so desires, but in such event only such dimensions, weight and construction shall be used as shall meet with the approval of the civil engineer in charge. The results obtained by using the steam hammer shall be carefully compared with the results obtained by driving with a drop hammer under the conditions imposed above, and the penetration of the last blow or any number of blows shall be determined by the civil engineer in charge. If required by the civil engineer in charge, in order to sink piles to the required depth, a water jet shall be used, without extra charge. The driving of a pile shall be continuous from the time of starting until the required penetration is obtained. The heads of all piles shall be hooped with iron rings during driving. If it is found necessary to furnish piles with metal shoes, the shoes will be furnished by the Government without extra cost to the contractor.

Heavy Swinging Dampers should be avoided in mechanical draft work, according to Mr. F. R. Still, of Detroit, in a recent paper in the "Journal" of the Western Engineers' Club. They should, he said, be cut up into small ones, as in a floor register, only not so small, say 12 to 20-inch louvers, with a rod connecting the louvers outside, so that they will all operate simultaneously.

The Failure of the Supply of Water in the Edison station supplying electricity for lighting and traction purposes for the City of Paterson, N. J., on Saturday evening, Sept. 6, caused the failure of three out of six boilers, resulting in the injury of two men and the interruption for an hour or more of the supply of electricity at a time of the week when it was, perhaps, most needed. Ordinarily the condensers draw water from a canal forming part of a hydraulic system that operates a number of mills in the city. Provision is also made for drawing water from the Passaic River, which is at a lower level than the power house and the boiler feed pumps may in addition to the two sources of supply already named be connected to the city mains. Owing to the closing of the head gates in the canal, it was empty and water was being drawn from the river at the time the accident occurred. The water was unusually low and, it seems, falling at the time. Before this was noticed the water got so low that the condensers and pumps failed to work and while investigation was being made as to the cause of their inaction the water became so low in the boilers that three of them failed. This experience would point to the desirability of providing, in places where the condensing water is lifted from a river or other source at a lower level, some automatic means of giving sufficient warning to prevent such accidents from occurring.

The New Power Plant for the Assabet Mills, Maynard, Mass.

The Assabet Mills at Maynard, Mass., which are owned by the American Woolen Company, have recently been enlarged by the construction of a new mill building for which power had to be provided. When this was planned it was decided to replace an old boiler plant with a new one, so that steam for the entire plant could be generated as economically as possible. The work was given to the company's consulting engineers, Messrs. Dean & Main, of Boston, and it has been constructed under their supervision. The Engineering Record is indebted to Mr. W. N. Wood, treasurer of the American Woolen Company, for permission to print the following description prepared from data furnished by Messrs. Dean & Main:

The new building measures 690 feet in length and 106 feet in width and is of five stories for half its length and six stories for the remainder. It is of the usual mill construction. Because of the fact that power could not be transmitted conveniently by belts from the engines to the shafting, the electric drive was adopted, and that made it possible to locate the engine room where most convenient. Steam for the old mill was generated in a battery of 12 horizontal return tubular boilers, each of 200 horse-power capacity located in a boiler house about 45x127 feet in plan. The chimney connected to these boilers was of good construction, 9 feet in diameter and 200 feet high, ample in size for a larger boiler plant. It was found upon investigation that these boilers could be removed, and, by raising the roof of the building, substitute for them 21 vertical fire-tube boilers, so that 4,725 horse-power could be obtained from them on their normal rating. Room remains for the installation of still another boiler, if necessary, so that the same building now accommodates 4,950 horse-power of vertical boilers instead of 2,400 horse-power in horizontal boilers as formerly used.

A plan of the boiler room as remodeled is shown in Figure 1. As the work had to be done without interruption to the operation of the mill, the method of making the change is quite interesting. The old battery of boilers occupied the space now taken by the new boilers indicated by even numbers. Vertical boilers numbered 1, 3, 5, 7 and 9 were installed while the older ones were in operation. The smoke flue for the new boilers was at a higher elevation than that for the old ones so that the new flue was put in without inconvenience. The new steam main was installed and connected and then six of the old boilers, in front of the new battery, were removed through an opening in the building wall. New boilers 2 to 10, which were more than sufficient in capacity to furnish all the steam needed, were then put in and the remainder of the old boilers in the north end of the building were removed through on opening made in the wall for the purpose. Afterwards new boilers 12, 14, 16 and 18 and 13, 15 and 17 were installed to supply power for the new mill. Room is left for boilers 11, 19, 21, 20 and 22.

The vertical boilers are a modification of the Manning type. They are of the same general design as those illustrated in The Engineering Record of July 2, 1898. They are internally fired with a fire box 5 feet high above the grates. The shells are about 8 feet outside the largest ring and the grates, 7 feet in diameter. The lower tube sheet is 5 feet above the grates, and there are 348-2¼-inch tubes in each boiler, each tube 15 feet long. An annular space of 15 inches exists between the tubes and the shell, so that a ladder, suspended by rollers at the top, can be run around a circular track riveted to the inner surface of the top of the shell, to permit a man to inspect and clean the tubes and shell. A manhole is placed in the boiler just above the lower tube sheet.

The total heating surface in each boiler is 2,965 square feet including 2,363 square feet of steam heating surface. The grate surface is 38.48 square feet and the ratio of the heating to the grate surface is 77 to 1. The boilers are intended to burn bituminous coal. The products of combustion pass to the chimney through a rectangular flue 10x5 feet in size and of uniform cross section. At a height of about 14 feet above the floor a continuous gallery extends along the fronts of each battery of boilers. The steam is delivered to two mains in the boiler room supported by stands opposite each boiler. The steam connection is carried around from the front of the boiler, then up into the bottom of the main, so that the triple bend this arrangement makes will provide sufficient elasticity to take care of expansion. A safety valve and a Chapman gate valve are placed in each of these feeders. The two mains are connected at the south end of the building by a cross-over pipe, from which a 15-inch main leads to the new power house. The old 10-inch main supplying the old engines is shown in the rear of one of the batteries in the longitudinal section. Before the old boilers were disconnected, a 10-inch connection with a Watts reducing valve was run from the new main to the old one as shown in the same drawing. The old system operates under a pressure of 100 pounds and the new one, 140 pounds. In case the reducing valve should become deranged, means are provided for relieving the pressure, should it become greater than desired, through a safety valve on the low pressure side of the reducing valve. A 4-inch blow-off main is connected to each boiler through a 2-inch globe angle valve and 2-inch straightway globe valve. It discharges into a tail race.

The new engine room is a brick structure 81 feet 6 inches by 44 feet 6 inches in size and is lighted by a double tier of windows on three sides. It is shown in plan and sectional elevation in Figure 2. It is equipped with a 15-ton hand operated traveling crane. Power is supplied by two McIntosh & Seymour, vertical cross-compound, condensing engines and one Ames engine, driving General Electric three-phase generators. The vertical engines are of different sizes, the larger one having cylinders 32 and 64x48 inches in size and a rotative speed of 120 revolutions per minute, while the smaller one has cylinders 20 and 40x36 inches in size with a speed of 133 revolutions. The economi-

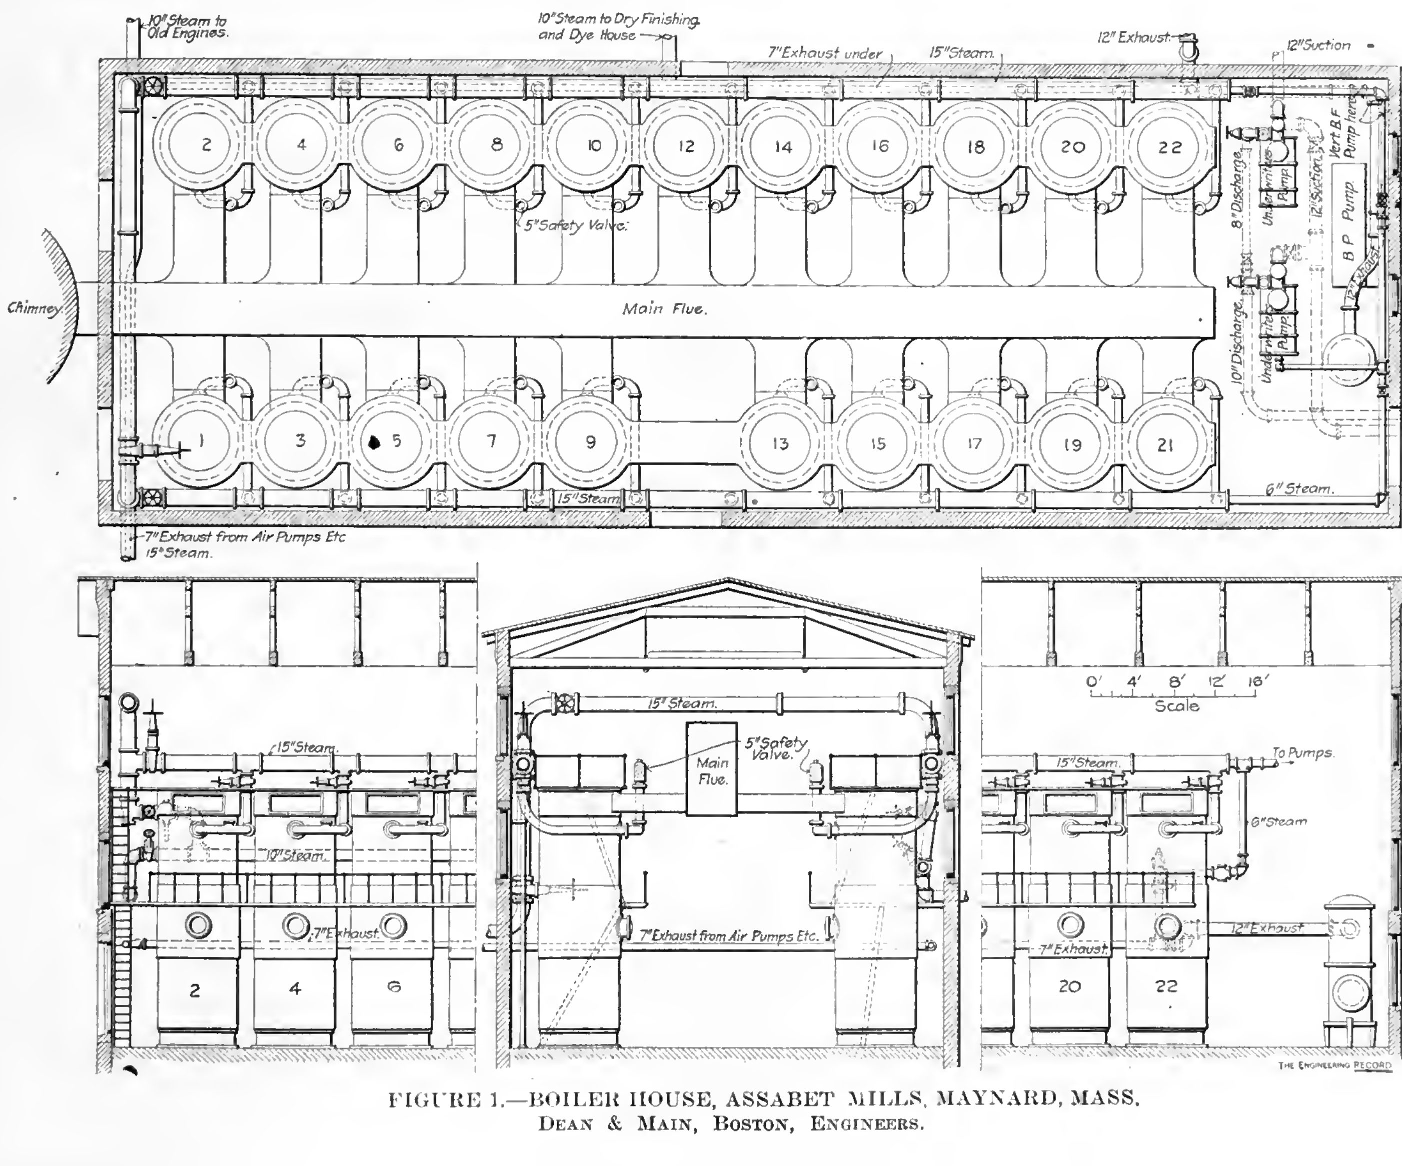

FIGURE 1.—BOILER HOUSE, ASSABET MILLS, MAYNARD, MASS.
DEAN & MAIN, BOSTON, ENGINEERS.

cal load of the former engine is about 2,230 horse-power, and of the latter engine, 760 horse-power. The large engine has bearings 23x48 inches, and the smaller engine 13x22 inches, with shafts 25 inches and 16 inches in diameter in the body, respectively. The steam pressure is 140 pounds. The two engines are provided with reheating receivers. The high-pressure side of the large engine and the reheater may be cut off at any time and the low-pressure side run with steam at reduced pressure, a connection with a Foster reducing valve being led directly to the low-pressure cylinder.

The larger engine drives a 2,000-kilowatt 40-cycle three-phase General Electric generator; the smaller one, a 500-kilowatt machine of the same frequency and type. When the main generators are in operation, the exciting current is supplied by a motor generator, operated by alternating current and delivering direct current. When this cannot be used through the main generators being shut down, or from any other cause, the exciting current may be obtained from a direct-current motor that may be directly coupled to a 14x14-inch engine made by the Ames Iron Works. This engine is of the center-crank type and is directly connected to a

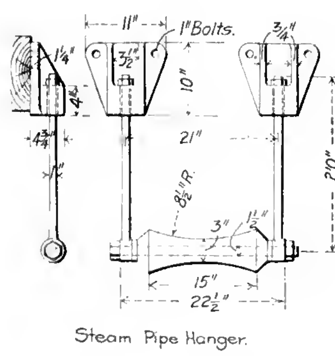

FIGURE 7.

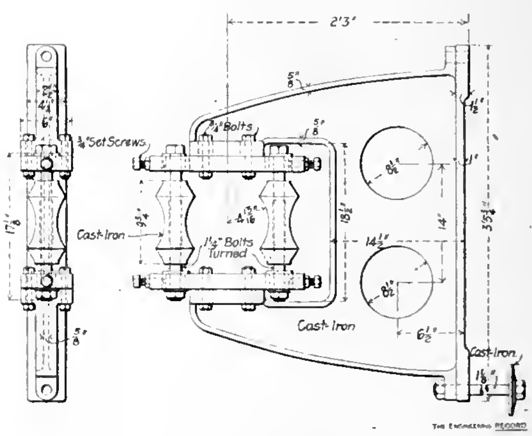

FIGURE 8.

DETAILS OF SUPPORTS AND HANGERS FOR PIPING.

100-kilowatt 40-cycle alternating-current generator used to supply the mill with small power during the night when the main plant is shut down. The exciting current for this is obtained from a small generator belted to a pulley on the out-board end of the engine shaft.

The main engines are intended to operate condensing and each exhausts into a jet condenser connected to a Warren vertical twin air-pump. The exhaust pipe from each engine is connected through a Blake relief valve to a common 18-inch free exhaust pipe. The injection water from the condensers is drawn from a pond through cast-iron pipes with bell and spigot joints. The pipe divides into two short horizontal branches leading to the condensers, and to provide for expansion, Wainwright expansion joints are placed in each branch. It will be noticed from the plans of the engine room that the air pumps discharge into a tee with an upward branch connected to a large vertical air chamber, this being necessary to reduce the shock, as the air pumps deliver the hot water under pressure to the dye tubs. Incidentally, there is saved by this utilization of the condenser discharge the large amount of steam that would be required were the usual practice followed of heating fresh cold water by means of live or exhaust steam. The air pump discharge passes through a 17-inch pipe to a large tank on the roof of the dye house. This pipe has a 6-inch branch leading to the boiler-feed pumps.

The exhaust steam from the air pumps and from the Ames engines in the new engine room is carried back through a 7-inch pipe to the boiler room, and there connects with a 12-inch exhaust from several non-condensing engines in the old mill. The 12-inch low-pressure pipe is connected with a 4,000 horse-power vertical feed-water heater, made by the Taunton Locomotive Manufacturing Company. Thus there is a low-pressure system, steadily maintained at a maximum by live steam through reducing valves, for use in the dye house and feed-water heater. A 2½-inch drain from the steam space in the heater is connected to a Geipel trap, which discharges into the blow-off from the water space of the heater. The steam that condenses in the heater is pumped into the boilers. There is a single steam connection to the heater, it being arranged on the induction principle, and an automatic air valve is connected to the top of the steam space of the heater to prevent it from becoming filled with air. A branch from the 12-inch exhaust mentioned supplies steam for heating and in case the supply of exhaust steam for these purposes is insufficient, for instance at nights when the engines are shut down, a 6-inch live steam connection is provided to meet this demand. The live-steam pipe has a reducing valve and a back-pressure valve, the latter to relieve the low-pressure system in case the pressure in it becomes too great.

There are two 1,000-gallon Underwriter fire pumps each capable of drawing water from the pond or city supply and discharging into the fire protection system, which consists of fire hydrants and the usual sprinkler equipment. There are two boiler-feed pumps, one a 14x8x18-inch Warren horizontal duplex outside packed plunger pump and a 12x7x12-inch Warren duplex vertical piston pump. One of the fire pumps is also connected to the bolier feeding system. Either of the boiler feed pumps may, independently of the other, draw water from three sources; the town supply, the pond or the air pump discharge. An American Steam Gage Company's Underwriter relief valve is placed on the pump discharge. The water is forced through the heater, which may be by-passed if desired, and thence to two 5-inch brass feed mains, one carried along the rear of each row of boilers, gradually reducing in size. A 2-inch branch, of brass, supplies each boiler, the water passing through a Chapman gate valve, a check valve, a union and plug cock in the order named. All high-pressure drips in the engine room, from steam pipes, jackets and reheating receivers, are collected into an automatic pump and receiver and returned by it to the boiler room, where it is delivered to both feed mains between the heater and the boilers.

An amount of attention that is unusual in steam plant construction has been paid to the steam piping and a description of its details will doubtless be of interest. The 15-inch mains in the boiler room are supported opposite each boiler by stands made of 6-inch pipes capped with cast-iron saddles. Each stand is bound by a 2½x⅜-inch strap bolted to the wall. Steam is carried almost 300 feet from the boilers to the engine room, and as there is a change in the direction of the pipe, the method of supporting it and taking care of the expansion is quite interesting. As shown by diagram, Figure 3, the pipe drops at the boiler room, then runs horizontally to the point B, where it rises about 8 feet. At C it changes its direction and extends about 190 feet to a separator in the engine room, at the point D. From A to B the pipe is supported by four roller cradles. At the bottom of the riser at B is a tee resting upon a brick pier. From B to C the pipe is suspended by five hangers each consisting of a roller turning upon a shaft suspended by two hangers 2½ feet long from a pair of 4-inch channels fastened at each end by angle clips to the floor beams. From C to D the pipe is supported by the building columns, by means of a bracket shown in Figure 4. The expansion of the pipe from A to C is taken up partly by the change in direction at the riser and by the flexible suspenders. The combined roller cradle and stand used between the points A and B to support the 15-inch main, the 6-inch exhaust pipe from the air pumps and the 2-inch high pressure drip return is shown in Figure 5. The two lower pipes are supported upon rollers and the upper one upon a stand resting upon three balls, the latter permitting a slight lateral movement as well as one in a longitudinal direction. At the opening where these pipes pass through the wall a covering plate is provided. This and an elevation of the support of the pipes is shown in Figure 6. Beneath the engine room floor the pipe is supported on hangers, shown in Figure 7.

At several points in the engine room the horizontal steam main is supported by a bracket of unusual design, shown in Figure 8. This is intended to allow motion in the direction of the axis of the pipe and vertical motion, but to prevent lateral motion or vibration. It will be noticed that the rollers may be brought to a firm bearing by means of the set screws at either end of the bracket, and while the pipe can move, there is considerable resistance thereto. The entire piping contract was executed by the Walworth Construction & Supply Company, of Boston. The specifications required that the exhaust piping should be equal to the Walworth standard for 100 pounds pressure, and that all flanges and fittings for the 100 and 140-pound work should be equivalent to the Walworth standard for 250 pounds. The "Walmanco" steam joint, made by the Walworth company, was used for connecting pipes in the high-pressure work. Corrugated copper gaskets washed with a thin layer of Dixon's plumbago paste were placed between the flanges, inside of the bolts, on the piping subjected to 140 pounds pressure and rubber gaskets on the exhaust lines. The gate valves with by-passes used on the high-pressure lines are of Chapman make with Crosby globe valves. The exhaust valves are Fairbanks.

The discharge from the condensers, as before stated, is partly used in the dye house and for boiler feeding. The pipe conveying the water is of cast iron with caulked lead joints. At the dye house the pipe reduces to 16 inches and from the tank the distributing pipes are of steel. To insure a constant head for the air pumps to work against, which was deemed necessary for their proper action, a discharge and overflow head was fitted to the top of the riser supplying the tank on the dye house roof. It is shown in Figure 9. The water rises through the central opening and overflows into the annular chamber A which is connected to the tank supplying the dye tubs. In case the tank is full and the demand of the dye tubs should be less than the discharge of the air pumps the water level in the chamber A rises and overflows into B which is connected to an overflow or waste pipe.

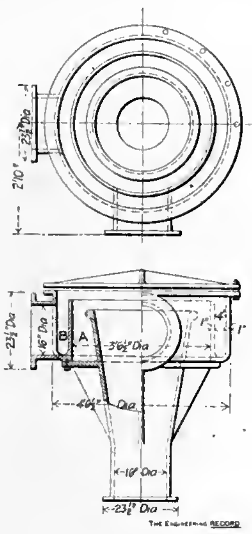

Figure 9.—Overflow Head.

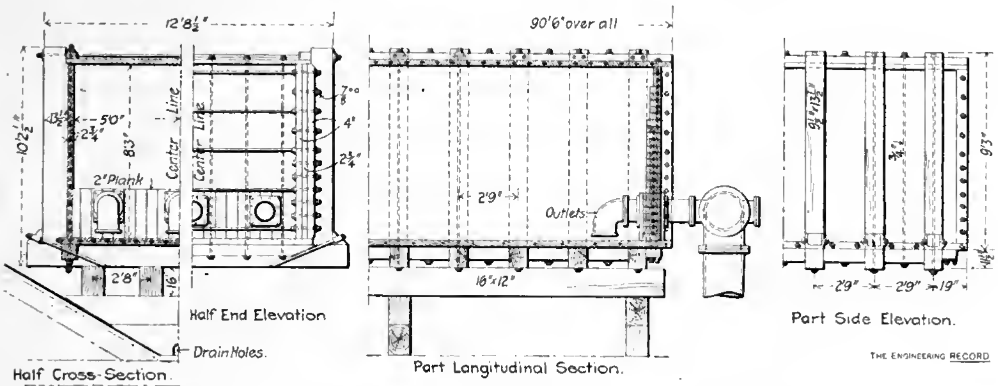

Figure 10.—The Water Storage Tank for the Dye Tubs.

The construction of the storage tank is shown in Figure 10. It is placed in the valley of the roof, as shown in the cross section. It has three 10-inch outlets connected to a header provided with a 20-inch supply to the dye tubs. The tank is 90 feet 6 inches in length over all, 8 feet 3 inches deep and 10 feet wide inside measurements. The bottom, top and sides of the tank are of Cypress with the joints spliced and laid in white lead. The sills are of 9½x11½-inch plain southern pine. The posts are of 9½x13½-inch pine, and each is tied in at the top by a pair of ⅞-inch bolts extending from one post to the opposite one. Straps hold them in place at the bottom. Other details are shown in the drawing.

The Cross Arms on the redwood poles commonly used for the electric transmission lines of the Pacific Slope are of 6x6-inch kiln dried Oregon pine, subjected to a temperature of 220 degrees Fahr. for several hours in a bath of asphaltum oil. The redwood poles are cut from young trees, not more than four from the one tree, and are counted on to last 25 to 35 years.

Submerged Pipe.

Abstract of a paper by A. L. Holmes before the Central States Water-Works Association.

In the larger cities along the navigable waters care must be taken that the pipe lines are beyond the reach of keels or propeller wheels and the pipe protected at the docks and landings. Then we must provide for the deepening of the harbors in the future, for the government is arranging for about twenty feet of water in all the principal lake ports, and pipes must go well out of the way of dredge dippers. About the only safe way for laying pressure pipes across navigable streams is to place them in a trench well below the bottom of the river and in this trench pipe carefully laid will give no trouble.

If the bottom is soft there is little trouble in dredging a trench, and if rock it can be drilled and blasted from the surface and the loose rock cleaned out of the trench, the most of it from above, but it will pay to send a diver down to be sure of a clean channel before sinking the pipe. In some localities with soft bottoms it has been a custom to lay the pipe on the mud with the upper ends disconnected, and then by a sand pump working along the line of pipe gradually work it down to place. It is obvious that where this can be done in sand or mud the pipe will keep in the bottom of the trench and save the handling of some material. Eternal vigilance is necessary in all this class of work.

At Michigan City, Ind., a 20-inch force main across the harbor was lowered from a depth of 16 feet 5 inches to a depth of 20 feet by the use of a sand pump and without any repairs whatever. This pipe was 160 feet long and was fitted with five ball joints, and together with 1,200 feet of other pipe on shore showed a leakage under 100 pounds of water pressure of only 168 gallons in 24 hours. A 16-inch riveted pipe across the stream at Hammond, Ind., was lowered in this way and by the use of a water jet and was perfectly tight when down. Of course this way of doing the work is not advocated where it is practicable to get and to maintain a trench otherwise, but some streams are so swift and carry so much fine sand or silt that the trench would fill as fast as dug.

The writer's preference for submerged pipe is cast iron hub and spigot with lead joints and every 36 or 48 feet a flexible joint that will allow of considerable movement. The Ward joint is perhaps as well known in this country as any of the various forms and was for quite a number of years the only one. During the last twenty years a half dozen others have come on the market and the price has been largely reduced. Originally in using the Ward joint, which is made in the end of 12-foot lengths of cast-iron pipe, it was the custom to use the whole line of submerged pipe of this kind, but this was not necessary and incurred a needless expense.

Wrought pipe is used to a large extent by private concerns, and there is a sufficient spring to a 6-inch wrought pipe with several joints to conform to a surface that is quite uneven. A flanged cast-iron pipe for this work will be expensive to lay and probably cause trouble from leaks.

With medium-size pipe, say up to 12 inches, the work of jointing and getting in place can be done from above water. In one case under the writer's charge a line about 200 feet long was sunk in 20 feet of water lowered from the sides of scows by ropes and showed no leaks at the time, neither has it in the eighteen years since placed.

Of course many, or the most of these lines, do leak unknown to the water works managers, and the best way to ascertain the amount of the leakage is by placing a valve at each side of a river crossing with a by-pass around it in which to place a meter. With the valves closed and a pressure on the meter the leak can be measured quickly. To locate the leak the writer has found the use of an air pump the most efficient and the quickest means. With the valves closed and the air under pressure introduced into the submerged pipe the air bubbles coming to the surface will locate the leaky joints very quickly.

In many streams where not interfered with by boats, pipes are jointed on a frame of timbers sloping toward the stream, and as each length is added the pipe is launched into the water, the outer end supported by floats, and as the pipe goes out floats are added about every 24 feet until the whole line is put together and it is then gradually lowered by long screws or ropes to the bottom. Twelve-inch cast iron pipe can be handled in this manner for about $1 per foot including the lead used for joints and it will cost about as much for the smaller pipes, and but little more for the 16-inch.

In some small streams and moderate depth of water the writer has used benches built of 2 by 6 and 4 by 4-inch timber set in the ground or bottom of the stream and putting the pipe together on these platforms easily lowered it to the bottom.

The placing of coffer dams and laying of pipe in them where practicable offers no objections to doing good work, but it is generally very expensive in operation, and the work at Ft. Wayne last year, where a 24-inch cast-iron pipe was laid across the St. Mary's River, is a fair sample of how long it may take to get in a few hundred feet of pipe in this manner.

In laying 24, 30 and 36-inch pipe in deep water the writer has connected 40 feet with lead joints in the usual manner, placing on each end of this section a half of a bolted ball joint and lowering this into the trench prepared for it, holding one end off the bottom with a piece of wood 8 by 8 inches placed under the hub as the pipe was lowered to place. The next section prepared in the same way is lowered to place and while in the slings and held just clear of the bottom the diver enters the ball into the bell and bolts it up and so the process is continued.

The pipe can all be put in shape to lower to the bottom in a harbor or where the work can be handled most economically, and it is often the case that 500 feet of large pipe is laid in this manner daily, which means that the work can be done cheaply and well. Bulkheads are placed over the ends of the pipes before they are placed in the water to exclude fish and rubbish while lowering and are removed by the diver and sent up for use again.

The writer does not advise an attempt to get pipe very closely in line. If it zig-zags a little it may keep tighter if it settles any. In river crossings a curve up stream is generally desirable, so that as the current washes out under it and it works down stream it will become tighter.

In suction pipes in lakes the writer advocates the submerged crib or intake and in most cases wood is cheaper and preferable for this purpose. In the great lakes, where there is navigation the outer end of the intake should be placed in 40 or preferably 50 feet of water. Ice drifts on to shore and piles up and sinks until it is 30 feet deep, and this must be watched and guarded against if possible. There is much less danger of obstruction to the water supply if a submerged crib is used than if it reaches above the surface. A crib of timber 24 feet square and 8 feet high, with a timber bottom and pockets loaded with stone, if no piles are necessary, can be placed for about $1,200.

Just as efficient protection is furnished by an upturned elbow on the end of the pipe in which is inserted a tee of the same size, the ends of which are barred, leaving openings about 3 inches wide. Around this drive 12 piles 10 feet in the bottom and cut them off 2 feet above the top of elbow, rip-rap about this to top of casting and it is as safe as if a lot more money was invested.

All intakes and suction pipes for large plants should terminate in a reservoir or pump well on shore, to which the water should flow, and while pipes should be so planned that the pumps can operate directly on the intake, yet it is better that the pump well or reservoir have screens to shut out all foreign matter and that they be large enough to allow sedimentation to take place if there is anything in the water.

All intake pipes should have valves placed at the outer ends and near the well with provision for closing both and testing, under pressure through a meter, for leaks and with air to locate them. Leaky suctions, whether on shore or under water, are the terror of the pump engineer and reduce the efficiency of his machinery and ruin his engines. A little care and persistency will find and stop the leaky pipes and save annoyance and coal bills. All suction and intake pipes should, of course, be laid to a grade that air pockets may be avoided.

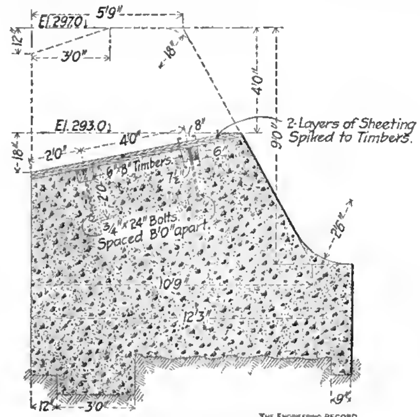
The writer would always insist on an efficient and easy way to test every pipe of this kind in use, and he considers that all submerged pipe should be looked upon with suspicion. He once removed an intake at Negaunee, Mich., laid in the bed of a muddy lake, the outer end in 30 feet of water, which, when laid ten years before, had been broken into five pieces, and which had sucked in the disease-breeding filth about 100 feet from shore and sent it through the town instead of getting the pure water through the 1,200 feet of pipe as intended. The experience at Duluth a few years ago where the intake was discovered broken in several places, and where typhoid was rampant evidently from this cause, is another instance. Neither could have happened if provision had been made for the test mentioned and it had been enforced as it should be.

A plant taking water from wells across a small pond from their pumping station sunk a line of spiral riveted pipe for a suction and could not lower the wells at all, but an outbreak of typhoid and an investigation and analysis of the water disclosed the fact that the water in town was identical with that in the filthy pond and entirely unlike the well water. Upon taking up this pipe, a connection was not only found through a tee with a check valve a few feet from shore, but some lengths of the pipe had let go or unwound, and the reason for the sickness and deaths was discovered.

"Out of sight out of mind," is apt to be the rule with submerged pipe, but if the water works managers will look after these under-water force mains they will in many cases find where a lot of the water they pump goes to, and if they will test their suction pipes going out to good water they will find them sucking in the filth and dangerous poisons in the mud near the shore and will find the reason for a good many disease germs found in water taken from the faucets when an analysis of the water at the intake shows nothing of the sort.

A Concrete Power Dam at Middle Falls, N. Y.

A water-power property at Middle Falls, N. Y., near Greenwich, Washington County, on the Batten Kill, was improved a short time ago by the erection of a concrete dam. The work was undertaken to replace a timber dam that leaked badly, but incidentally the opportunity presented itself of raising the level of the impounded water 4 feet with a corresponding increase of the working head and the advantages of added storage capacity. The enlarged flooded area that would result from the extra height of dam, however, gave promise of numerous legal complications, and these rendered it unadvisable to continue the construction as originally intended. The dam having in the meantime been partially completed, the work was continued on the original lines, stopping at the height of the former dam; the structure has thus been left so that it can easily be completed at such time as is found expedient. For its height the dam is consequently a very substantial one. The improvement was planned by Mr. Henry Floy, of New York City, in an interesting manner, as shown in the accompanying drawings.



SECTION OF THE DAM.

The water is diverted to each side of the stream for a pulp mill on one bank and various mills and an electric lighting and power station on the other, the owner of the latter, the Consolidated Electric Company, controlling the entire water power. Two waterways had thus to be maintained, and a dam was built across the stream with gate structures or abutments at each end, with a rollway in the center 114 feet long and two wing dams running downstream from each end of the rollway portion separating each waterway from the stream proper. The wing dams are somewhat similar to the rollway portion of the main dam and are designed to afford 165 feet additional rollway in times of high water. As shown in the accompanying plan of the dam, the abutments are not in a straight line with the main rollway section, but all parts, including the wing dams, are arranged to have a mutual bracing effect. The main dam is curved upstream on a 450-foot radius.

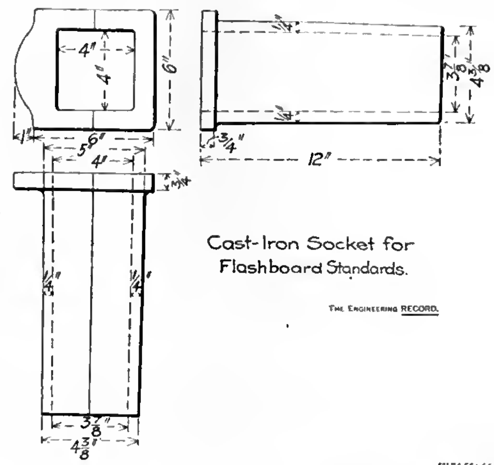
A section of the rollway is shown herewith. The design of the full-size dam contemplated an upward inclined approach to the dam crest, at an angle of about 18½ degrees with the horizontal to prevent the lodgment of debris and a downstream face with curved top and bottom, as shown. As completed, a double layer of sheeting spiked to longitudinal timbers fixed to the top of the dam, was used, giving an approach angle of about 11½ degrees with the horizontal. A cut-off is provided at the toe of the dam and a larger one at the heel, these cut-offs being in both wing dams as well as in the main rollway dam and the abutments. The wing dams differ from the main rollway section in that there is no inclined approach to the crest, as racks in front of the gates keep out large floating bodies, such as ice and logs. The area of the cross-section of the dam is about 90 sq. ft., so that allowing 145 pounds per cu. ft. for the concrete, the weight of the dam is 6.5

tons per lineal foot; when carried to its full height it would weigh 8.7 tons per foot. In connection with the full-height dam, it is intended to use flashboards by which 4 feet additional head can be obtained. The flashboard structure is to be set in sockets imbedded in the dam crest, 3 feet 3 inches from the upstream face of the dam and on 5-foot centers.

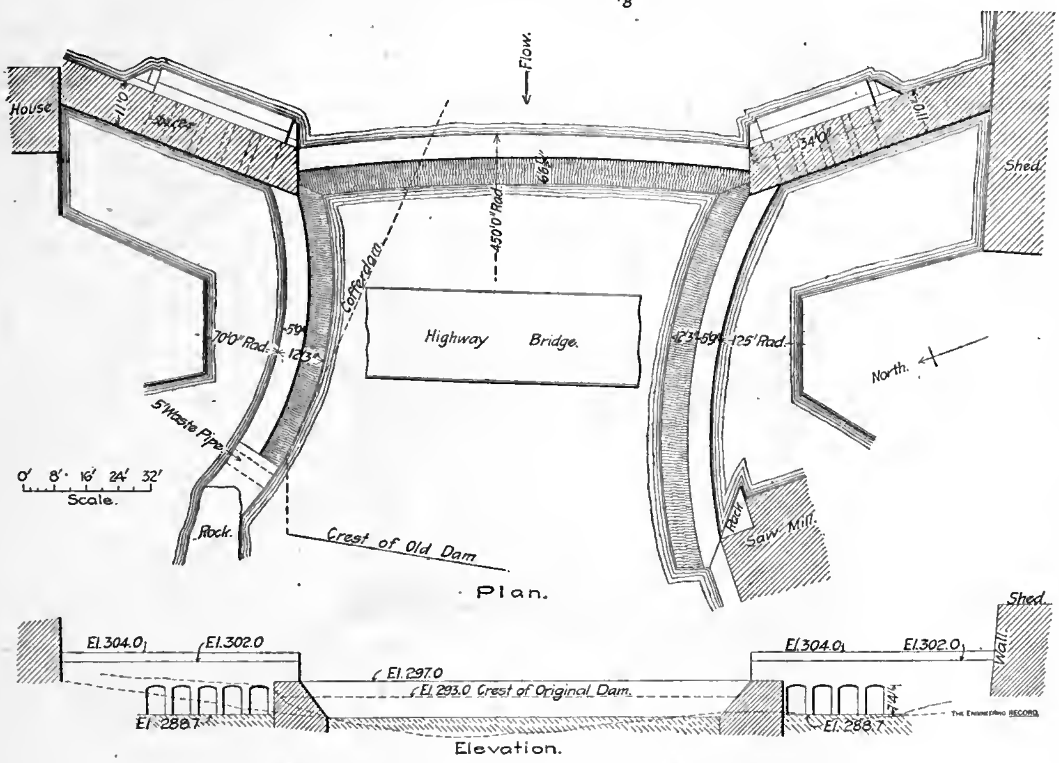
The gate structures or abutments are not as thick through as the bottom part of the dam, being 11 feet, but are heavier, having vertical up and down-stream surfaces and carried to an elevation 11 feet above the present dam crest, or 7 feet above the desired dam height. The gate structures in each case run to the stone foundations of a building on the river bank. In one case there are four openings and in the other five, each 5 feet wide and 7 feet 4 inches high and each provided with the usual protection rack of iron bars to keep out debris. These are of ¼x3-inch iron mounted in a usual way on an inclined I-beam framework. Each opening has a lift gate of 4x12-inch timbers, one gate in each side operated with geared crabs for opening against heavy pressure, as when first admitting water, the rest lifted by simple crabs. The water in each case flows through the waterways, which is a basin confined between the wing dam and the corresponding shore. One of the difficulties of the work was encountered in this connection, in providing sufficient area of waterway, which, indeed, partially accounts for the curvature of the wing dams. Between the old dam, the location of which is indicated, and the new dam, are located the abutments of a highway bridge. The flow of diverted water had on both sides of the stream to be taken around these abutments, and to secure the maximum possible area, the rock was cut away as far as safe around the abutment foundations. The bottom of the gate openings is at elevation 288.7, so that with water at elevation 293, that is, at the height of the rollways, the total wet area of the openings on the right bank of the stream is 107.5 square feet and on the other, 86 square feet. The large size of openings was made to provide for handling high water over the wing dams. The section of the waterways between abutment and wing dam was taken large enough so that the maximum rate of flow of water is 5 feet per minute. Attention should be called to the fact that the rock sides of the abutment foundations were smoothed with concrete; while, of course, the other side is the smooth wall of the wing dam. Each basin has a 5-foot drain pipe for emptying it.

To build the dam, cofferdams consisting of timber cribs filled with stones, were run from the old dam upstream, and the main rollway portion and one gate structure and its corresponding wing dam were first built. The water was then allowed to pass through the completed gate structure and basin and over a portion of the completed dam, while the gate structure and the wing dam on the other side of the stream was constructed behind cofferdams. As already stated, the dam throughout is built entirely of concrete, in the following proportions: one part of Atlas Portland cement, three parts sand and four parts of gravel in varying sizes, being taken from a convenient bank. Some Glens Falls cement was employed toward the end of the work. A hand and gravity concrete mixer was used and the material was carried to place in wheelbarrows. The dams are built on the trap rock of the stream bed. The total cost of the work was about $20,000.

The electric plant is supplied with McCormick turbines built by the Rodney Hunt Machine Company. They drive two two-phase Stanley generators, one of 120 kilowatts capacity, at 1,000 volts, and 66 cycles, installed in 1898, and the other of 330 kilowatts capacity, at 2,500 volts and 60 cycles, erected in 1901.



Cast-Iron Socket for Flashboard Standards.



Plan of the Water Power Improvement at Middle Falls, N. Y.

Sewage Disposal Works at Nuneaton, England.

For many years the system of sewage purification adopted at Nuneaton, England, was chemical precipitation and artificial filtration, but the results were not altogether satisfactory, and the working expenses very high; so that it was decided several years ago to make a trial of the bacterial system with septic tanks and contact beds. Although the sewage was particularly difficult to deal with on account of the waste matters discharged into it from the works of wool scourers, fellmongers and hat factories, this trial proved so satisfactory that the treatment was applied to the whole of the sewage, resulting in a very considerable saving in working expenses.

These works having become inadequate to properly deal with the increasing quantity of sewage, an entirely new arrangement of the works was undertaken last year by the engineer, Mr. J. S. Pickering, Assoc. M. Inst. C. E. Both the old and the new plans were described in detail by him at the meeting of the Association of Municipal and County Engineers at Nuneaton last fall.

In the first arrangement of the bacterial system the sewage was passed through a screening chamber to a pump well 50 feet deep. From this it was pumped into two roughing tanks, each 20 feet in diameter and 13 feet deep, where the heaviest part of the suspended matter was deposited and lifted automatically to within 2 feet of the surface by the pressure of the sewage. This sludge was dealt with in two Johnson's sludge presses.

The sewage then flowed into septic tanks or coarse contact beds. There were three open septic tanks and one closed one, each of a capacity of 120,000 imperial gallons. An area of 1,708 square yards of coarse contact beds was provided, and in order to test the qualities of the various materials, these beds were filled with coke, macadam, broken pots, ashes and broken bricks. The sewage remained in the contact beds about two hours. From the tanks and coarse beds the sewage passes into the fine contact beds, of which there is an area of 3,564 yards, varying from 3 to 5 feet in depth and composed of coke dust, coke breeze, small coal, and fine granite chippings. From these beds the effluent passes directly into the river. It is stated that the coke beds gave the greatest capacity, but there seemed to be no appreciable difference in the results obtained from the various materials used, as regards their purifying power.

The closed septic tank was in use for over two years without being emptied, and it had liquefied during that time about 95 per cent. of the suspended matters passed through it. It was found necessary to empty the open septic tanks after 7 to 9 months' working, when the sludge from the three tanks produced about 320 tons of pressed cake. It is stated, however, that while the flow through the closed tank was only about 50 per cent. of its capacity, the open tanks had to deal with a quantity equal to 150 per cent. of their capacity. A coating of scum was not found to be a necessity for the proper working of the tanks.

As regards the odors arising from sewage treatment, Mr. Pickering is of the opinion that a system of open septic tanks cannot be carried on without a considerable nuisance, and that the least offensive method is by the Dibdin system of coarse and fine contact beds. He does not agree with some authorities that after reaching a certain stage the capacity of contact beds will remain undiminished, believing that sooner or later the beds must become choked to a considerable extent.

As an illustration of the saving in sludge pressing resulting from the introduction of bacterial treatment, the amount of pressed cake in tons per million imperial gallons was for the years beginning with 1897 and ending with the first eight months of 1901, 18.1, 16.8, 10.7, 5.4, 3.3. The average quantity of sewage treated was in October, 1901, about 750,000 imperial gallons per day, having nearly doubled in a period of eight years.

In the new plan the works just described are utilized as a pumping station and for the treatment of storm water. The sewage is pumped about 2½ miles to the new site, where, after screening, it passes through detritus tanks, through coarse and fine bacteria beds and is finally passed over an irrigation area. By this arrangement the use of sludge presses was entirely dispensed with. The estimated cost of these works was about $219,000. They are designed to treat 1,500,000 imperial gallons of sewage per day, about three times the dry weather flow. When the pressure in the pumping main reaches that due to the delivery of this volume, a relief valve is automatically opened at the pumping station and the excess up to six times the dry weather flow is taken care of in the old beds.

Upon reaching the new site the sewage passes through two revolving wire screens 5 feet wide, having ¼-inch meshes and driven by a water wheel propelled by the sewage. It then flows through three covered tanks built on the Dortmund principle, 34 feet deep and 24 feet in diameter, with a combined capacity of 150,000 imperial gallons. The matter intercepted in these tanks is automatically discharged by the pressure of the sewage and is delivered into furrows on the irrigation area, and incorporated with the soil.

The site chosen for the bacteria beds is 20 acres in extent and has a natural slope of about 40 feet, thus enabling the tanks to be built in terraces. Fourteen concrete tanks were constructed—seven for the coarse material and seven for the fine. Each bed has an area of 1,000 square yards, and the depth of material averages 4 feet. Assuming the material to occupy two-thirds of the space in the beds, the remaining one-third gives a capacity of 75,000 imperial gallons to each. As they may be filled and emptied three times daily, they are capable of dealing with a total quantity of 1,575,000 gallons per day.

Each of the coarse beds is provided with three inlets, and at each of these a fine screen is placed. This special screening is rendered necessary by the large quantity of wool fiber contained in the sewage. The sewage is distributed over the beds by means of open-jointed socketed pipes laid over the material. The material for the coarse beds is broken granite, about 2½-inch gauge. The beds are drained by means of U-shaped, butt-ended tiles, laid 4 feet apart. After contact in the coarse beds the effluent is conveyed to the fine grain beds, which are composed of screened coke dust. This material, although somewhat finer than that generaly used, has been found to answer admirably.

From the fine grain beds the effluent is discharged on to the land, an area of 60 acres having been acquired for this purpose. The carriers consist of 18-inch stoneware pipes, laid below the ground, the effluent rising in chambers at intervals of 30 to 40 yards, for distribution over the land. These pipes work under a head of 4 or 5 feet. The land, which is mostly of a gravelly nature, is under-drained to a depth of about 5 feet. The upper half of the sockets of the main drains are made with a cement joint, the lower portions only being left open. The drains were placed in the first instance about 40 yards apart, with a view, if found necessary, of laying intermediate drains.

The Strength of Concrete-Steel.

In a recent communication to the Paris Académie des Sciences, M. Considère describes a series of valuable experiments carried out by a commission appointed by the Ministre des Travaux Publiques, with a view to ascertaining the precise role played by the metal in ferro-concrete constructions. According to an abstract of the report in "Engineering," the specimens tested by the commission were generally 6.56 feet long, and had a cross-section 3.94 inches square. Each of these concrete bars was reinforced at the corners by four steel rods, having a total section of 0.177 square inches. The concrete employed was made by mixing 661 pounds of Portland cement with 1.04 cubic yards of gravel, passing a 0.98-inch screen, and 0.52 cubic yard of sand, passing a 0.19-inch screen. It was found that in setting, the contraction of the concrete gave rise to an initial compression in the steel reinforcement amounting to 2.86 tons per square inch of the metal. The corresponding tensile forces simultaneously called forth on the concrete amounted to 74 pounds per square inch. Tested in tension, it was found that the specimens stretched rapidly until the stress on the concrete was practically equal to the ordinary tensile strength of this material. From this point the tested bar stretched much less rapidly, and throughout this period the tensile stresses in the concrete remained constant, the whole increase of load being taken by the iron bars. It follows, therefore, that during this period the elastic modulus of the concrete was zero. In one case the test-bar was subjected to a stress of 292 pounds per square inch of cross-section, under which the total extension of the specimen was 0.024 inch. The reinforcing rods were then cut out, and the +-shaped bar left was then tested in cross-breaking, and in spite of being somewhat injured in the cutting out of the reinforcing bars, only failed under a calculated stress of 128 pounds per square inch. Summing up, M. Considère states that concrete-steel submitted to tension acts precisely as ordinary concrete, so long as the tensile stress does not exceed the usual breaking stress of ordinary concrete. Under higher stresses it will support without breaking extensions which, in the case of specimens hardened under water, have been as great as 1/500th the total length; and, in the case of air-hardened concrete, have ranged between 1/2000th and 1/850th of the total length. When the concrete-steel is stretched beyond the usual elastic range of ordinary concrete, the tensile stress on the concrete remains constant up to the ultimate breaking-point, the whole of the additional load being taken up by the metal. When subjected to repeated tensile stresses, however, the fraction of the load carried by the metal tends to augment, and that of the concrete to fall, until ultimately the working stress on the concrete is only 70 per cent. of its original value. If finally, after a series of loadings and unloadings, the maximum load is raised 30 per cent., the concrete again exerts a tensile resistance equal to its primitive value. It may be added that the modulus of elasticity in compression of a concrete-steel bar is reduced on stretching the latter.

Repairs to Asphalt Pavements in Toronto, Can., according to the 1901 report of city engineer, C. H. Rust, were carried out under contract at $1.23 per square yard for 2½-inch surface, $1.09 per square yard for 2-inch surface, and $4.75 per cubic yard for concrete foundations.

The Philadelphia Company's Building, Pittsburg.

The Philadelphia Company is a corporation owning, operating and supplying natural (fuel) gas for heat and power, artificial gas for light, electricity for light and power, and street cars for transportation in the cities of Pittsburg and Allegheny and surrounding territory. It is now erecting in Pittsburg a steel cage office building designed exclusively for its own occupation. It has a front of about 35 feet on Sixth Avenue, a depth of about 150 feet on Garland Alley and is designed for an ultimate height of fifteen stories although it is to be roofed at present just above the ninth story floorbeams. The general features of design and the details and connections of the steel work conform to the standard practice for such structures which have been frequently illustrated in The Engineering Record, but there are some special features of foundations, columns and roof construction which will be described in this article.

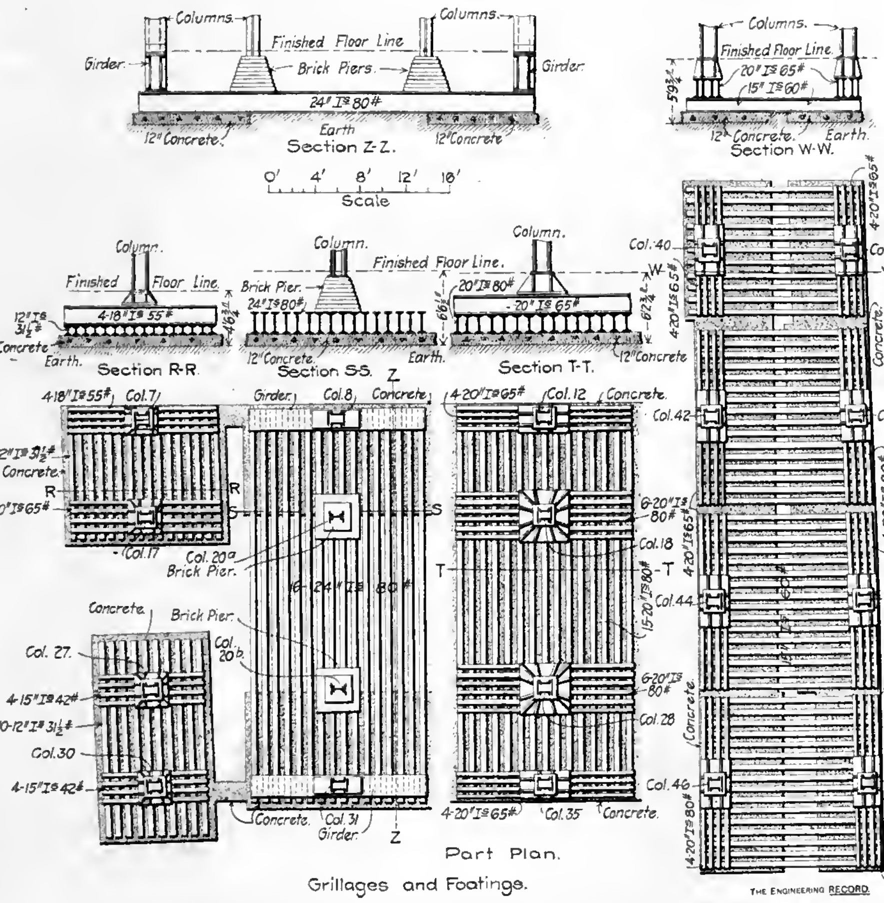
A horizontal wind pressure of 20 pounds per square foot on the whole surface of the outer walls of the building is assumed, and it is calculated that this will be resisted by solid-web knee braces between the wall girders and columns and by the stiffness of floors and partitions, the rigidity of the beam and column connections, and by the inertia of the heavy completed structure. The total weight of the eight-story building and contents is estimated at about 10,000 tons and that of the building and contents if extended to a height of thirteen stories at 15,000 tons. These amounts are distributed as uniformly as possible over a large percentage of the total area of the lot and on portions of the adjacent street areas beyond the building lines. The foundations have concrete footings laid on the bottom of the general excavation for the basement, and covered with steel grillage beams which receive the column loads through distributing beams or girders below the basement floor level.

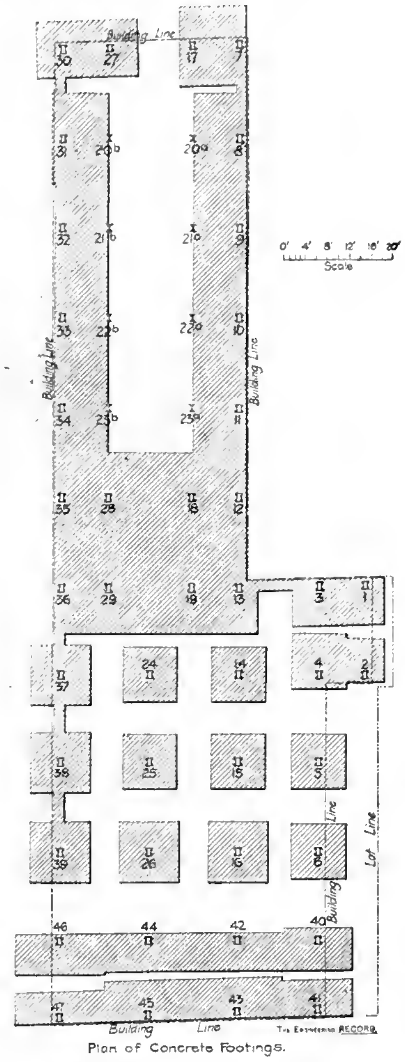
The finished basement floor level is 12 feet below the curb and it was originally intended to carry the excavation only about 6½ feet deeper and make the concrete footings of a uniform thickness of 1 foot. It was found, however, as the work progressed, that the surface mould was underlaid by muck which was not suitable to receive the footings and the excavation was continued through it to the earth and gravel below. The excavation did not extend to ground water level, and was not deep enough to require unusual provision for retaining walls. It was, however, made after the materials had been ordered for the columns and it was impossible to carry their bases to a lower level, therefore the whole excavation, up to the grillage beams, was levelled up with a solid mass of concrete not originally contemplated nor needed as a footing, which acts merely as a filler and reaches in some places, not shown on the accompanying drawings, to a depth of over 6 feet.

The arrangement of the concrete footings varies in different parts of the building, as shown in the general plan, but in general there is a continuous strip of concrete 27 inches wide and 1 foot thick under the outside walls which connects the adjacent footings, although this is omitted in some places. At the rear a footing from 6 to 8 feet wide and about 62 feet long extends across the lot and 5 or 6 feet beyond it at both ends and distributes on the earth the loads from the wall columns. Parallel to it and from 1 to 3 feet away in the clear, is a corresponding footing of similar dimensions for the first row of interior columns. These two footings are entirely separate except that they are connected by the grillage which they support. This is composed of 15-inch 60-pound transverse I-beams 12 inches apart on centers and about 16 feet long which are divided in three groups of 16 and one of 11 beams, separated 18 inches. Each group carries 80-pound longitudinal I-beams across it at each end to distribute on it the column load received through a cast iron pedestal 20 inches high with its base extended to rest across the flanges of all four longitudinal beams. By this arrangement each grillage beam becomes a double cantilever, unsupported and unloaded, in the center, between the two footings, and having the distributed loads of the footing reactions applied to the lower side and the concentrated loads from the distributing beams applied in the opposite direction to the upper side. The distributing beams are figured for a loading which consists of the reaction from the grillage beams distributed over the whole of their lower sides and the concentrated column load in an opposite direction in the middle of the upper side.

The next three transverse rows of interior columns have separate footings 10 feet square, on each of which is set a grillage of nine 12-inch 31½-pound transverse I-beams 9 feet long and 13 inches apart on centers. Across the centers of these beams there are four 15-inch 42-pound longitudinal distributing beams, 9 feet long and 10 inches apart on centers. The columns have cast iron pedestals 3 feet square and 14 inches high seated on the centers of these upper beams. Columns 1, 2, 3, and 4 have footings, grillages and distributing beams corresponding to those already described in the rear of the building for columns 40 to 47; the remainder of the footings are in the narrower front part of the building. Columns 7 and 17 are supported on the same 12x14½-foot footing which has grillage beams carrying distributing girders at both ends so as to provide for uniform and symmetrical loading from columns located at the opposite edges of the footing. The 10½x18½-foot footing for columns 27 and 30 has the centers of the sets of distributing girders set back 5 feet from the ends of the grillage beams but otherwise corresponds to the foundation last described.

The remaining twenty-four columns, 8 to 36, have their grillages supported on a continuous bed of concrete which forms a single U-shaped footing extending nearly the full length of the narrow front part of the building and having a width equal to the distance between building lines. The two branches of the U are 10 feet wide and 64 feet long with a clear space of nearly 16 feet between them. At one end they unite to form a solid rectangle 33 feet long and nearly 36 feet wide. It was under this footing that the excavation had to be made deeper than was originally intended, to reach soil of a satisfactory bearing capacity, and the space below the basement floor between the footings is backfilled with sand and earth thoroughly rammed in 12-inch layers. The surface of this footing is entirely covered by 94 24-inch 80-pound transverse grillage beams about 37 feet long and 12 inches apart on centers. They are divided into four groups of 16 beams each and two groups of 15 beams each. The 16-beam groups have double-web distributing girders across each end and the 15-beam groups have sets of longitudinal distributing beams across them at both ends and at two intermediate positions. In both cases the wall columns are supported over the extremities of the grillage beams and their loads are uniformly distributed over the concrete footings.





FOUNDATIONS OF THE PHILADELPHIA COMPANY'S BUILDING, PITTSBURG.

In each of the transverse rows which include wall columns 8, 9, 10 and 11, there are two light interior columns which extend only to the first floor and have their bases seated on brick piers which rest directly on the grillage beams. The corresponding interior columns 18, 19, 28 and 29, are of full size, extend to the top of the building and are seated on longitudinal beams which distribute their loads to all the grillage beams in their respective groups. All the grillage beams are thoroughly painted and carefully bedded in concrete or Portland cement mortar and are connected by cast iron separators and ¾-inch tie rods about 5 feet apart. Concrete is filled in solid in the spaces between all beam and girder webs and extends 4 inches beyond all their sides, ends and flanges so as to thoroughly enclose and protect them. Selected moist earth and sand was rammed around and above all groups of beams and all girders, and levelled at sub-grade where 6 inches of concrete was laid on it for the basement floor. All cast iron column bases are below the basement floor level and are enclosed in concrete like the beams and girders.

The building has 47 main columns reaching from foundation to roof, and eight short columns, which, as already mentioned, reach only to the first floor and have I-shaped cross sections made with a web plate and four flange angles. The main columns are all made with closed rectangular sections having two channels and two cover plates. They are made in three sizes, with 12-inch channels and 16-inch plates, with 15-inch channels and 16-inch plates and with 15-inch channels and 22-inch plates. Each column reaches from the basement to the ninth tier of beams in three sections, spliced 21 inches above the finished floor lines of the third and sixth stories with milled butt joints and two opposite plates 2½ feet long on top of the cover plates. These plates are shop-riveted to the lower and field-riveted to the upper sections of the columns. At the third floor splice where the sizes of the upper and lower column sections do not change, the milled ends of the column channels and plates are in direct contact, but at the sixth floor where the channels change from 15 to 12 inches there is a horizontal diaphragm plate ¾ inch thick interposed between the abutting ends to give bearing and distribute the pressure uniformly and the flanges of the smaller channels are fillered out to the width of the wider channel flanges.

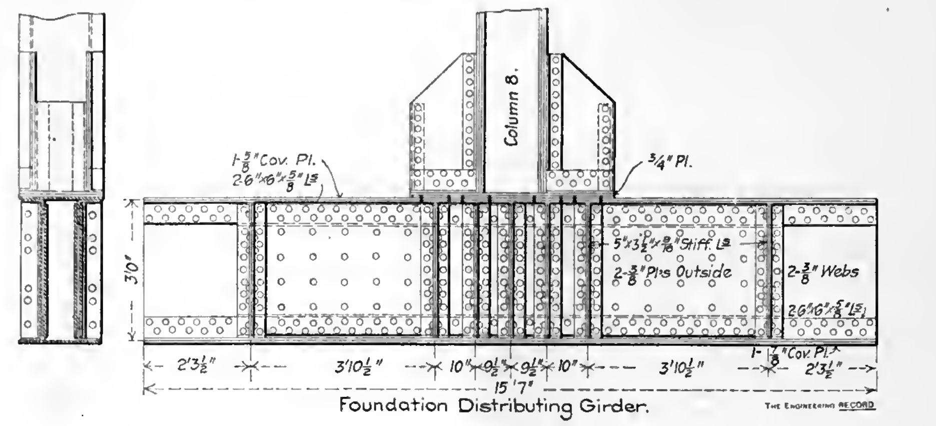
Columns 18, 19, 28 and 29 are designed for maximum loads and have 92½ square inches cross sectional area, made up with two 15-inch 40-pound channels, two 16x1-inch plates and two 14x¾-inch plates. In the lighter columns of the upper tiers the cover plates are omitted and the channels are latticed together, thus reducing the cross sectional areas to a minimum of 17.6 square inches. The columns are proportioned for a unit stress of 16,000 pounds per square inch, reduced by column formula, and the foundations are calculated for a maximum pressure of about 6,000 pounds per square foot on the earth.

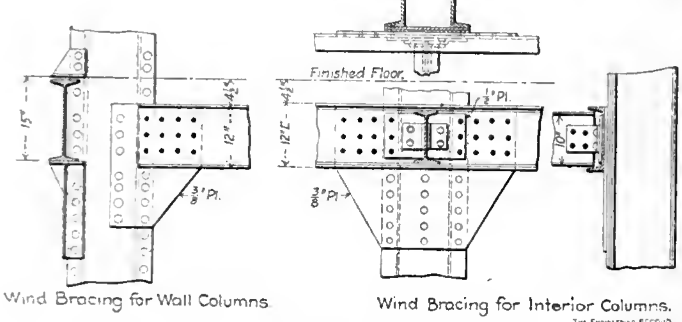
Columns 8, 9, 10, 11, 31, 32, 33 and 34 are seated on double-web distributing girders and are connected to their top flanges with vertical field rivets through long narrow base plates, as shown in the detail drawing. They distribute the column load by means of wide reinforced gusset plates on each side which extend the column base and practically increase the depth of the distributing girder. All other columns have base plates like that shown for column 7, which extend a few inches each side of the column face, and are seated on the cast iron pedestals below cellar floor level.

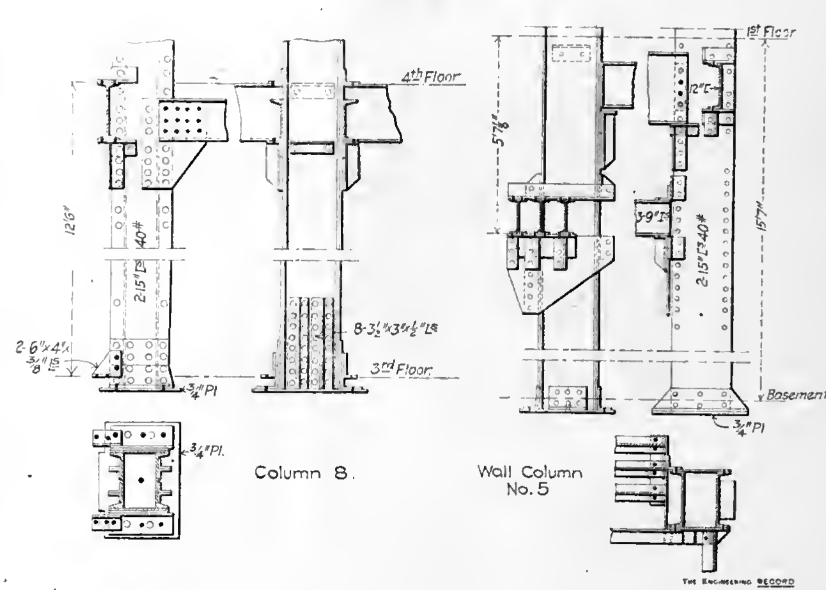
The location of the first tier of columns is shown on the footing plan. In the first and second stories the eight columns, 20, 21, 22 and 23 A and B, are omitted and the wall columns carry the whole superstructure and leave the full width of the building unobstructed in the narrow portion. Above the second story there are four columns, 20, 21, 22 and 23, midway between the pairs of wall columns 8-31, 9-32, 10-33 and 11-34 respectively. Except where the girders are used as wind braces the beams and girders are connected to the sides and faces of the columns in the usual way with horizontal angles across the upper and lower flanges and with the lower angles reinforced by vertical flange bearing and distributing angles, as shown on the column details.

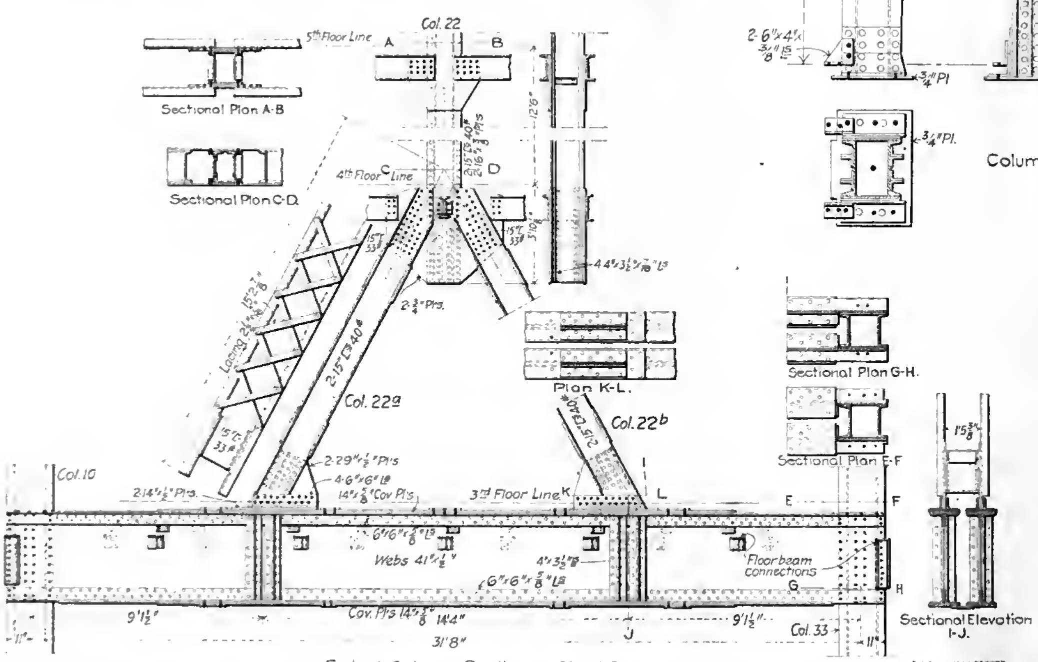
In each story, except a part of the third, the transverse floor girders, parallel to the short sides of the building are made double and have their column connections designed to resist lateral wind pressure and deformation of the transverse vertical panels of the columns and beams. This construction terminates at columns 13, 14, 15, 16, 42 and 43 and does not extend to the row of columns from 3 to 41. The special girders are in all cases 12-inch 30-pound channels with the backs of their webs riveted to gusset plates on opposite sides of the columns as shown in the wind bracing details. The channels are continuous across the interior columns; at the wall columns they are cut only long enough to take the regular rivets through the column channel flange. All the floors are of hollow brick proportioned for a load of 150 pounds per square foot except in the first story where it is 200 pounds and the beams are 12-inch 31½-pound I-beams about 5 feet apart and of about 16 feet span. The beams in the other floors are the same except that they are generally 10-inch 25-pound I-beams. The wall girders are 12 and 15-inch I-beams bracketed out from the faces of the columns as shown in the details.

In the basement there extends nearly from column 9 to 19 a fireproof vault with its axis coincident with the center line of the building. It is about 59 feet long and 16 feet wide and to insure its protection from falling bodies in case of a possible fire in the upper stories of the building it is covered, just below the first floor, by a series of 101 transverse horizontal 12-inch 31½-pound I-beams set 7 inches apart on centers and connected by tie bolts and separators, with the spaces between their webs filled with concrete to make a solid massive slab. Between columns 18, 19, 28 and 29 the vault wall construction is carried up to the roof, and independent fireproof vaults about 16 feet square are formed with special floors at every story.









Structural Details of the Philadelphia Company's Building.

A hall about 32 feet wide and 80 feet long and 24 feet high is provided free of obstructions in the front of the building by removing all interior first and second story columns opposite wall columns 8, 9, 10 and 11. The intermediate pairs of wall columns 8-31, 9-32, 10-33 and 11-34 carry the whole weight of the six upper stories which are now built over the hall and are proportioned to carry that of the seven additional future stories planned for. They are connected in the third floor tier by double plate girders which support the row of center columns 20, 21, 22 and 23 which, if the building is extended to the proposed height of fifteen stories will have maximum loads of 242 tons each. Carried in the center of a 32½-foot span these loads would produce heavy moments and it would be desirable to support them on trusses; these would require to be the depth of a story and would involve at least the obstruction of a full partition entirely across that story. This was architecturally undesirable and it was calculated that a plate girder shallow enough to be contained in the floor space without too deep a projection beyond the ceiling below would weigh about 20 tons. This was considered an extravagant use of metal and involved difficult and expensive erection work.

The problem was finally solved by terminating the columns at the fourth floor and carrying their loads from that point to the third floor girders by double inclined lower sections like pairs of batter posts or braces resembling an inverted V, as shown in the drawing of the assembled columns and girder. The distance between the feet of the inclined posts was made about 15½ feet from out to out so as to be as wide as possible and still clear the corridors in the sides of the building. The inclined posts are concealed in a partition through the center of the story so that no serious obstruction is occasioned, and the moments are very much reduced so as to effect a great saving of the metal employed to transmit the loads to the wall columns and permits the advantageous use of shallow plate girders. These girders are 3½ feet deep with solid webs and the usual I-shaped cross sections. The top flanges are flush with the third floor tier of beams and the bottom flanges project about 24 inches below the ceiling line and are enclosed in mouldings which divide the ceiling of the large hall into panels.

The girders are in pairs about 3 inches apart in the clear and are not connected by their flanges, which have entirely independent 14-inch reinforcement plates for each piece. The upper parts of the lower story wall columns extend up between the girder webs and terminate at the top flange where they have cap plates extending across the girder flanges to receive the bases of the third story sections of the columns. Each girder is connected to the wall columns by 40 single-shear rivets through each end of the web and through the column cover plate. The inner edges of the lower flanges of each pair of girders are connected by small tie plates and the upper flanges are connected by the inclined column sections. Separate base plates are shop-riveted on the top flange of each girder and have jaws made with pairs of wide connection angles which receive between their vertical flanges the connection plates which are shop-riveted to the webs of the inclined posts. The upper ends of the inclined columns are field-riveted to wide and thick jaw plates on the feet of the fourth story column sections. Each girder in the pair weighs about 6 tons and was easily hoisted about 30 feet and connected in place.

Although the present height of the building is only eight stories the upper tier of columns is three stories high like the rest and terminates at the standard height of 18½ inches above the ninth floor line. The ninth floor tier of beams corresponds with the other upper tiers and this floor and the ceiling below are built on it in readiness for the future extension of the building. The tops of the columns are covered by horizontal diaphragm plates and the upper tier columns can be readily connected to them by removing the diaphragms, cutting out the upper rivets in the cover plates and driving regular splice plate rivets in their holes.

An ordinary steel-frame roof house is built on the ninth story floor-beams in the front of the building; elsewhere there is a flat-pitched roof sloping transversely about 1: 24. The highest part of this roof is about 2 feet 9 inches clear above the finished ninth floor and it is supported by single 3½x3½-inch vertical angles set about 5½ feet apart on the transverse beams of the ninth floor tier. Seven longitudinal horizontal lines of 6-inch channels and I-beams are seated on top of these vertical angles. They have spans of about 16½ feet, are about 5½ feet apart and are spliced by double web plates close to each vertical. They are connected by tie rods about 2½ feet apart and support a hollow brick arch and tile roof. The tops of the vertical angles are braced transversely by single lines of 6-inch channels riveted across them just below the longitudinal I-beams and pitched to correspond with the slope of the roof.

Messrs. MacClure & Spahr, of Pittsburg, are the architects of the building and Mr. S. C. Weiskopf, New York, is the consulting engineer. The Thompson-Starrett Company, of New York, are the general contractors and the detail drawings for the steel superstructure were made under the supervision of Mr. George Simpson, assistant engineer, of their staff. The structural steel for the first eight stories weighs about 1,200 tons and was rolled by Carnegie Steel Company and fabricated by the American Bridge Company, Mr. Paul L. Wolfel, chief engineer.

The Central States Water Works Association Convention.

The sixth annual convention of the Central States Water Works Association, held in Indianapolis, was called to order September 23, by Joseph J. Pater, President, of Hamilton, O. Hon. Chas. A. Bookwalter, mayor of the city, welcomed the visitors. President Pater, after a brief response, referred to the objects of the Association, the necessity for constant vigilance in maintenance of a pure water supply, and the desirability for some measures being taken to remedy the growing evil of pollution of streams, which must always remain the principal sources of supply for towns and cities.

The convention was in session three days, and although there was considerable transpiring to distract attention, in the fact of the reunion of the Spanish-American war veterans and the reception to President Roosevelt, considerable business was done. A large number of new members were received and a new departure taken in admitting associate members to the same privilege of voting and holding office as enjoyed by the active members. It is expected that this liberal action will tend to greatly benefit the Association, which is already indebted to the associate members for many courtesies. A resolution was also adopted that the members so far as possible give preference to associate members in the purchase of supplies, other things being equal. The reports of the Secretary and Treasurer showed the finances of the Association in healthy condition. Mr. A. J. Pray, of the Pittsburg Meter Co., located at Columbus, O., reported upon a design for a button and certificate, both of which were approved and adopted. Mr. Fred Baker, of Evansville, Ind., offered some valuable suggestions looking to increase of membership, including the establishment of a bureau of statistics to be in charge of the Secretary. The suggestion was adopted and will be at once carried into effect.

Officers for the ensuing year were elected as follows: Joseph J. Pater, Hamilton, O., President; Frank J. Kelley, Cincinnati, O., Vice-President; Frederick Baker, Evansville, Ind., W. H. Glore, Covington, Ky., T. H. Morton, Nashville, Tenn., A. L. Holmes, Grand Rapids, Mich., S. F. Tompkins, Joliet, Ills., and O. G. Guyton, Sistersville, W. Va., State Vice-Presidents; Wm. Allen Veach, Newark, O., Secretary; Chas. E. Rowe, Dayton, O., Treasurer; C. H. Wiles, Delaware, O., Geo. F. Cooper, Xenia, O., Jerry O'Shaughnessey, Columbus, O., Executive Committee; T. R. Cook, Toledo, O., John Langan, Tipton, Ind., A. W. Inman, Massillon, O., Finance Committee. Dayton, O., was selected as the convention city for 1903.

Among the papers presented was one by Mr. John Langan, Tipton, Ind., on "Flushing the Mains." He places at the lowest point of his system 150 feet of 8-inch sewer pipe leading to the bluffs of an adjoining water-course; by opening a valve here and closing certain valves in the central portion of the city the current is changed through any desired line, and thus better results are obtained in flushing mains than through hydrants. Mr. Charles, of Lexington, agreed with the writer; he uses "wash-outs" and condemns flushing through hydrants.

Mr. C. E. Inman, Warren, O., presented a paper on "Automatic Sprinklers," discussing the proper charge for such service; users claim the sprinklers are not employed except in case of fire and should not be charged for any more than the general use of hydrants on streets is charged for in fires; also that the installing of sprinklers saves greater expenditure of water and labor of firemen by preventing progress of fires; and therefore no charge should be made. Manufacturers who take water for other purposes want this sprinkler service free because they pay for other water used; insurance people require a much larger main to supply sprinkler services, and object to meters as obstructing passage of water through services. The writer commented on the disadvantages attending sprinklers in the temptation afforded to surreptitious use of water, and thought on account of the large reduction in insurance rates users should pay for this protection. The discussion following indicated great diversity in practice as to charges for this class of service, some cities deriving no revenue at all from it. Messrs. McIlhenny, Cooper, Cook, Kelley, and Davis gave their experiences. The Indianapolis Water Company was charging $50 for 4-inch, $35 for 3-inch, $25 for 2-inch, and other cities were charging from $25 to $300 for such protection. Users in Indianapolis had acknowledged a saving of from $1,800 to $3,000 in individual cases. Care should be taken in putting in sprinkler systems that street mains are of sufficient size, and that in case of fires where walls fall the surrounding property shall not be cut off from water supply. As a result of this discussion a resolution was adopted that an equitable charge should be made by cities or private companies for such protection; and a similar resolution was carried calling for an equitable charge to be made for standpipes, private fire services, etc. It was conceded that in this latter case the unauthorized or surreptitious use of water was more likely to occur than with sprinklers.

Mr. J. R. Maxwell, C. E., of Hyde Park, Cincinnati, O., presented a paper on "A Method of Testing Wells Connected to the same Suction or Supply Pipe," describing a propeller wheel with spiral openings similar to those of the small electric fans in common use, with a solid rim made nearly the diameter of the pipe to be tested, leaving room enough to revolve freely without touching the inside of the pipe. A light steel rod is connected with the spiral wheel and carried up through cap to top of pipe; a meter is attached to register the revolutions of the spiral wheel.

Mr. S. A. Charles, of Lexington, Ky., read a paper on "Eighteen Years Experience in the Purification of Water," explaining his method of regulating mechanical filters applicable to smaller cities where because of the cost other systems are objectionable. He uses an auxiliary pump, driven by the main pump and maintaining a certain known ratio of velocity to the main pump, to inject a solution of sulphate of alumina of any required strength. He also employs æration to remove odor due to algæ or decomposing vegetable matter, his water supply being from a pond of still water. The water is delivered to the filters through a pipe or tube perforated with about 1,600 minute holes, through which it falls in spray on the filter below. One-third of a grain of sulphate of alumina per gallon was used on an average the year around; the cost per 1,000 gallons being one cent, covering all expenses. The bacterial efficiency was 98 to 99 per cent. He used only the very best grade of sulphate of alumina, the cheaper quality being useless.

Mr. F. A. W. Davis, vice-president of the Indianapolis Water Co., submitted a paper on "Fire Streams," prefacing it with the explanation that he had had his attention especially invited to this subject by reason of the bringing of suits against cities and private companies in event of fire losses on the ground of insufficient pressure and water supply. He gave figures showing amount of pressure required at hydrant to deliver through hose of a given length and throwing a stream a certain distance. He demonstrated the importance of using the least possible length of hose, and having nozzles the requisite size. Too small nozzles were often used, and hose improperly laid so as to increase friction. Firemen must also understand the proper use of fire hydrants, which were sometimes not fully opened. He suggested the feasibility of constructing larger fire engines of greater capacity to be placed on cars to run on street-car tracks, using motors to run the car and drive the pumps; such pumps to throw a stream of at least 3 inches. In the discussion following Superintendent Bosch criticized the employment by firemen of nozzles of ¾ to ⅞-inch, and the laying out of too much hose. Superintendent Cook, of Toledo, called attention to the improper handling of hydrant valves, and said he had exhibited a section of a fire hydrant in the fire headquarters at Toledo, accompanying it with an explanation to firemen how to use hydrants properly. Superintendent Pater commented on the mistake made by many cities in laying too small mains.

Mr. Marshall Leighton, Hydrographer, U. S. Geological Survey, Washington, D. C., presented a paper on "Stream Pollution and its Pecuniary Damage to Natural Water Resources," in which he reviewed the subject and invited the cooperation of all water works men in certain efforts the Government is now making which will tend to remedy the evil complained of. The following paragraph gives the kernel of the paper:

"It will be my endeavor as the official in charge of this new branch of the survey work to establish a system of co-operation with every chemical laboratory in the United States, wherever the analysis of water is conducted. It is desired to bring together the results of water examinations for study and comparison, such examinations to be made according to standard method, so that there may be uniformity of data. Coincident with this work the areas of special interest throughout the country will be taken up and studied. This has already been accomplished in the metropolitan district around New York. Similar work is now being carried on in the anthracite coal regions of Pennsylvania, and during the coming winter the drainage area of the Wabash river will receive attention. In the performance of this work I shall be glad to take counsel of the members of this Association and shall be grateful for any and all assistance."

The paper by Mr. C. W. Wiles, of Delaware, O., on "Street Sprinkling Wagons" was brief but very much to the point. He favorably mentioned the attachment of a meter to these wagons. A law has recently been adopted in Ohio placing street sprinkling in the hands of the city authorities and providing that by petition of 35 per cent. of the voters such streets may be ordered sprinkled as they desire, the cost for maintenance to be assessed on the tax duplicate.

Mr. A. L. Holmes, of Grand Rapids, Mich., gave a paper on "Submerged Pipe," most of which is reprinted elsewhere.

Appreciating the importance of the subject of electrolysis, at the suggestion of President Pater a motion was adopted to republish the papers contained in last year's proceedings of this Association on Electrolysis by Mr. Edwin P. Matthews, city solicitor, of Dayton, O., and Mr. L. Clifford Anderson, of Franklin, O. The latter gentleman gave a short address upon the general subject of electrolysis as affecting underground structures, and gave valuable advice to those who might be called upon to dictate terms of franchises to street railway companies looking to the protection of water pipe.

The Max Joseph Bridge in Munich, which is now rapidly approaching completion, is a three-hinge masonry structure with a clear span of 210 feet, a thickness of 3.45 feet at the crown, a rise of 19.7 feet from the springing to the crown and a rise of 26.2 feet from the abutments to the crown. It carries a 39.3-foot roadway with a 9.8-foot sidewalk on either side and has a total length, with approaches, of 298½ feet. Limestone has been used for all parts save the bearing stones of the steel hinges, which are granite. About 6,500 cubic yards of

concrete were employed. The foundations required 15,500 bags of Marienstein cement, and the arches 2,700 bags of Dyckerhoff cement. About 1,800 cubic yards of limestone were used in the arch. According to the "Centralblatt der Bauverwaltung," the bridge was finished, outside of the decorative features, in about 200 working days, and 600 men were employed during the work. Columns designed by Professor Fischer, of Stuttgart, will be erected at each end and provided with bronze bas-reliefs. The builders are Sager & Wörner; the engineer's name is not given.

The Sewage Disposal Works of Salford, England, deal with 2,000,000 imperial gallons of sewage daily. Chemical precipitation followed by filtration through clinkers is the purification process in use. The precipitants used are lime and sulphate of iron, each in the proportion of 550 pounds per million imperial gallons of sewage treated. From the sludge tanks 600 tons of sludge daily is forced by Tangye sludge pumps into a sludge steamer which carries it out to sea beyond the mouth of the Mersey. After passing through the roughing tanks and settling tanks, the settled liquid is distributed over the filters by means of brass sprinklers fixed at intervals on top of horizontal pipes crossing from side to side of each section of the filter beds at intervals of 8 or 10 feet. There are 4,500 of these sprinklers for the whole area of 26,000 square yards. They throw up the liquid in a hollow cone, the drops falling in a fine rain over a circle 4 or 5 feet in diameter. The upper stratum of the filter bed is composed of clinker which has passed through a ⅜-inch screen. At present it has a depth of 5 feet, but it can be raised to 7 feet. Below this is a bed of coarse clinker 1 foot thick, resting on concrete. Although the sewage of Salford contains much foul trade refuse, the results of the treatment just described are considered, according to "The Builder," to be very satisfactory, the effluent being odorless and clear, and averaging well within the standard of the Joint Board of the Irwell & Mersey watershed. Mr. J. Arnold is the engineer in charge.

The New Westinghouse Foundry at Trafford City, Pa.

The rapid growth of the affiliated Westinghouse industries was recently signalized by the creation of a new city and the building of another Westinghouse manufacturing plant. The new industrial center is located about 17 miles east of Pittsburg on the Pennsylvania Railroad and is to be known as Trafford City. Extensive factory sites have been laid out here to provide for the overflow of the several Westinghouse industries, a number of which have already used up all the available building room at their present locations and are still pressed for space. The first of the corporations to erect buildings in the new city is the Westinghouse Foundry Company, which is at present putting up the extensive foundry plant and pattern shop described in this article. This addition is necessitated by the rapidly increasing business of the Westinghouse Machine Company especially in connection with very large steam and gas engines and steam turbines. Before taking up the foundry itself, a short account will be given of Trafford City.

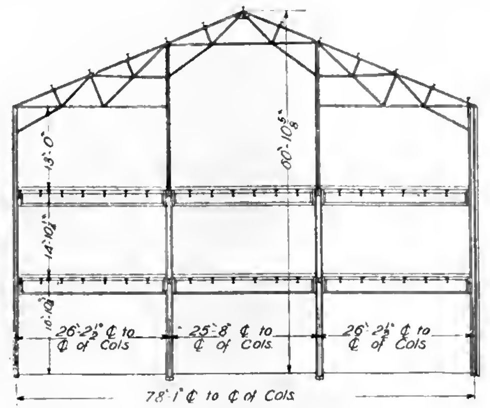
In laying out this city, provision has been made, not only for the factories that are to be erected there, but also for homes and all modern improvements and comforts for the men who are to work in the factories. The latter will be located on a fairly level area between the Pennsylvania Railroad and the residence portion of the city, which will be reached from the railway station by a steel viaduct 1,100 feet long. The residence district has been laid out upon hillsides and a generally level plateau, high enough above the factory sites to render it free from smoke and dirt. The city consists of two oblong areas, one of which is about ½ mile by 1/5 mile and the other ½ mile by 1/7 mile, the two areas meeting in such a way as to form a reversed letter L, the corner of which is the most northerly part. The town has been laid off into about 800 building lots, each with an average frontage of about 30 feet and a depth of 100 feet. In addition to this, space has been left for six parks. The entire town has been provided with waterworks and a sewerage system, the latter including separate storm water and sanitary sewers. This work, as well as the paving of the streets, was completed before the city was thrown open to settlement. The latter event, which took place on June 7, 1902, recalled in many ways the famous booms of the far West. Many of the intending purchasers of the lots came to the site of the future city a day before the sale was to commence and "squatted" on the ground which they wished to possess.

The new town is connected with Pittsburg by the Pennsylvania Railroad, over which there are 46 local passenger trains going each way daily and reaching the center of the city in from 25 to 35 minutes. In addition a street railway line has been built, connecting with the Pittsburg Railways Company's line at Wilmerding, 2½ miles distant. This street railway passes over the steel viaduct into Trafford City and forms a loop through the principal streets.

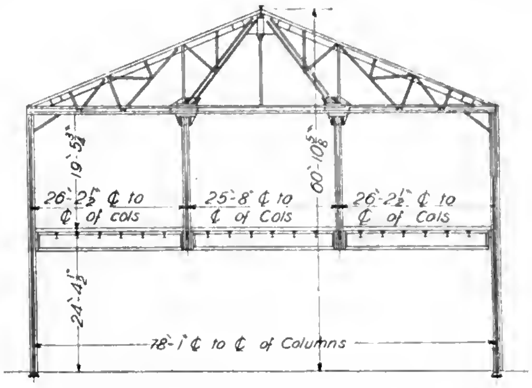
The factory site, located in a bend of Turtle Creek, provides room for nine factory buildings, each about 200x800 feet. A system of railway yards and tracks serving this area has been laid out in a very thorough manner, providing a track alongside of each building and transversely through each end. The storage tracks, in connection with this, occupy an area of about 300x200 feet. This system of tracks is connected with the main line of the Pennsylvania Railroad by the Turtle Creek Valley branch of the latter. It is, also, to be connected with the towns of Wilmerding and East Pittsburg, where the works of the Westinghouse Air Brake Company, the Westinghouse Electric & Manufacturing Company, and the Westinghouse Machine Co. are located, by an interworks railway which will be operated by the Westinghouse interests.

The new foundry and pattern shop of the Westinghouse Foundry Company, which, as stated above, are at present being erected, are located at the extreme southern portion of the factory site and near the steel viaduct mentioned above. The pattern shop and storage building, which has already progressed well toward completion, is a steel and brick structure 605 feet long and 80 feet wide, with a height to the eaves of the roof of 47 feet. The pattern shop occupies 160 feet at one end of this building. It is divided into two floors, the second floor being suspended from the roof trusses in order that the first story may be entirely free from columns, thus providing ample space for handling the largest patterns. The remaining 447 feet of the building is to be used for the storage of patterns and has three floors, the two upper floors being supported on steel columns and the entire space being divided by interior fire walls into three separate compartments. The foundations are of concrete and the superstructure of steel and brick. The foundation of the ground floor is made up of 8 inches of concrete into which the floor sleepers are bedded and on top of these is a layer of 2-inch maple flooring. The upper floors in both the pattern shop and storage building are supported on steel beams and steel girders, and are made up of 3-inch yellow pine flooring covered by one thickness of maple flooring. The roof purlins are steel I-beams spaced 8 feet center to center, and covered with 3-inch roof sheeting which is covered with slate.

The foundry building is 611 feet 8 inches long and 184 feet 3 inches wide outside of the brick walls, which are 36 feet high at the eaves and 80 feet at the peak. As in the case of the pattern shop, the foundations are built of concrete and the superstructure of steel and brick. The foundry is divided transversely into three bays, the center bay being 80 feet 3 inches wide between centers of columns, runways being provided for travelling cranes of 80-foot span and 150 tons lifting capacity. The cranes will be electrically driven. The two side bays are each 50 feet 6 inches wide from center to center of columns and are provided with runways for traveling cranes of 47-foot 2½-inch span and 50 tons lifting capacity. At one side of the foundry building runways are provided for yard traveling cranes of 100-foot span and a lifting capacity of 75 tons. The I-beam purlins are spaced 8 feet center to center and are covered with 3-inch yellow pine roof sheeting. The roof is covered with slate.

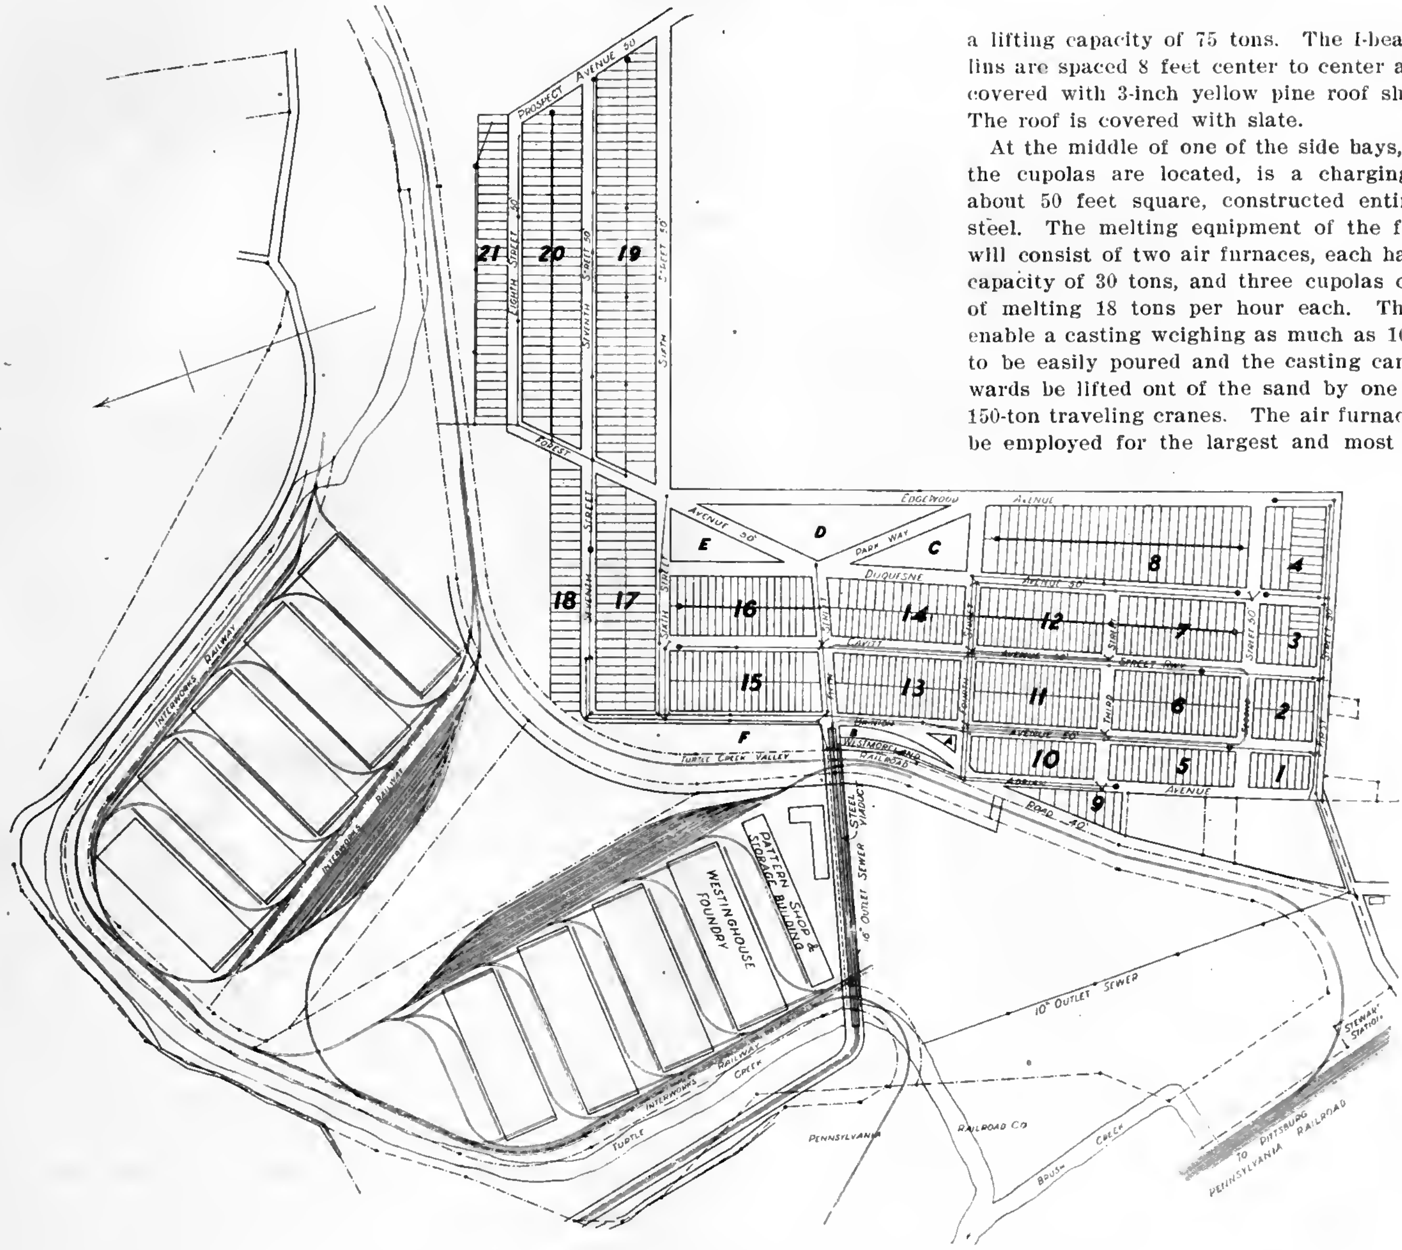


Pattern Storage.



Pattern Shop.

At the middle of one of the side bays, where the cupolas are located, is a charging floor about 50 feet square, constructed entirely of steel. The melting equipment of the foundry will consist of two air furnaces, each having a capacity of 30 tons, and three cupolas capable of melting 18 tons per hour each. This will enable a casting weighing as much as 100 tons to be easily poured and the casting can afterwards be lifted out of the sand by one of the 150-ton traveling cranes. The air furnaces will be employed for the largest and most important castings, owing to the fact that they yield a superior quality of iron, and the cupolas will be employed for the ordinary classes of castings, and particularly small castings. The building will contain every modern convenience known to the art, making possible the easy and economical handling of all materials, and it is expected to produce such castings as those re-



GENERAL PLAN OF THE SHOP PROPERTY AND RESIDENCE TRACT, TRAFFORD CITY, PA.

quired for the largest size of steam engines now in existence, with provision for possible increase in sizes for the future. Both buildings will be provided with automatic sprinklers for fire protection.

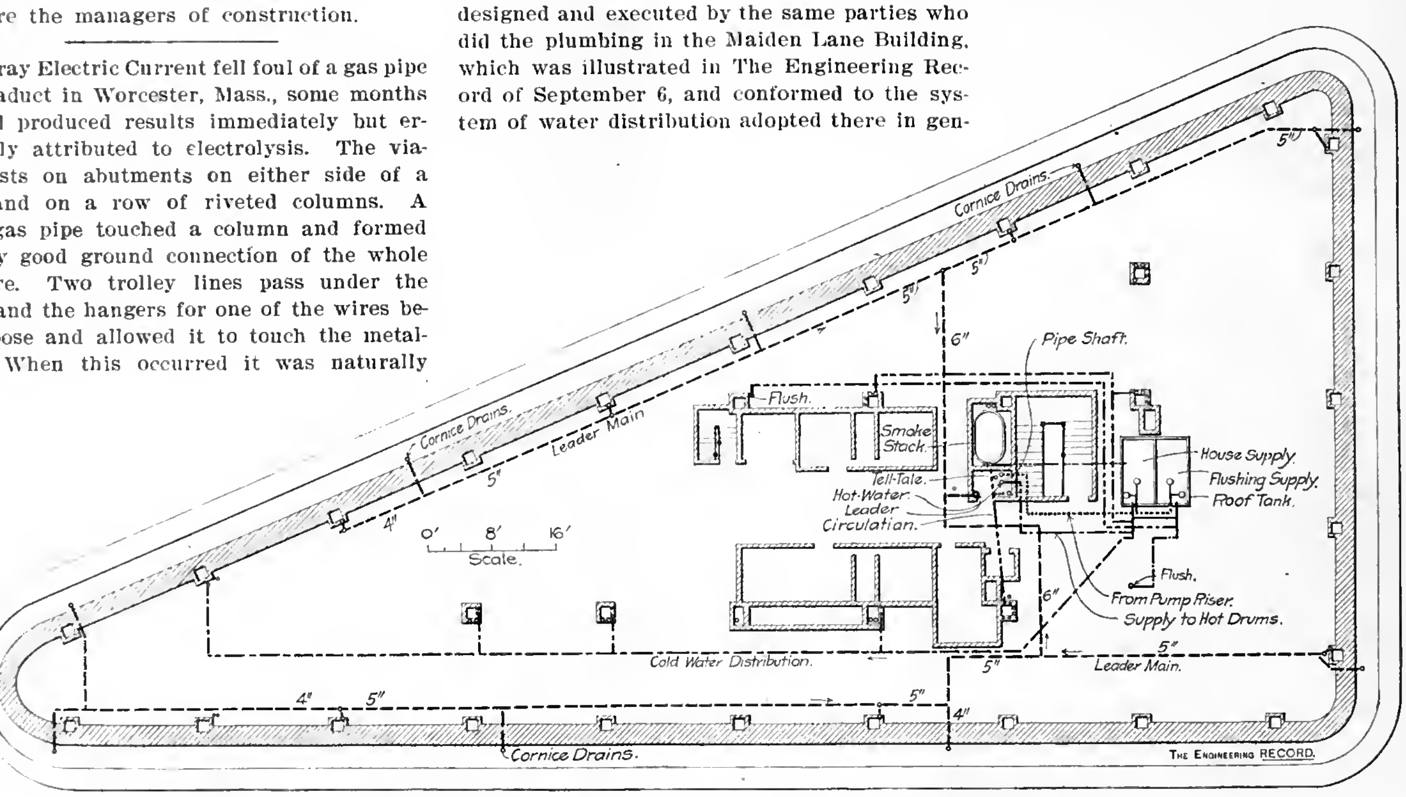
The buildings will be equipped throughout with modern lavatories and conveniences for the comfort of workmen and will be in every respect up-to-date. They will be heated by hot air, the foundry, pattern shop and pattern storage rooms to have minimum temperature of 50, 60 and 35 degrees Fahrenheit, respectively, in zero weather. Artificial light will be furnished by both arc and incandescent lamps. In order to insure plenty of light during the day, the windows are large and both the foundry building and pattern shop are provided with skylights of large area. The plans for the buildings were prepared under the supervision of the Westinghouse Machine Company. The Security Investment Company of Pittsburg is the financial agent and general contractor for the entire works, and Messrs. James Stewart & Company, of St. Louis, Mo., and Pittsburg, are the managers of construction.

A Stray Electric Current fell foul of a gas pipe on a viaduct in Worcester, Mass., some months ago and produced results immediately but erroneously attributed to electrolysis. The viaduct rests on abutments on either side of a street and on a row of riveted columns. A 2-inch gas pipe touched a column and formed the only good ground connection of the whole structure. Two trolley lines pass under the bridge and the hangers for one of the wires became loose and allowed it to touch the metalwork. When this occurred it was naturally troublesome to keep the circuit breaker in place in the power house, for a large part of the current was passing into the earth through the pipe. An investigation was started which showed that about 3 feet of the gas pipe was practically burned out and the cement in one of the joints was fused into glass.

Hand Sweeping Machines were used in Washington with marked success during 1901-02, according to the annual report of Mr. Warner Stutler, superintendent of the street cleaning department. Previous to the adoption of the machines, 210 men cleaned with hand brooms 1,565,800 square yards of street daily; with the machines the same force cleaned 1,920,400 square yards. The extra cost of cleaning this larger area was $3,265, but if the work had been done by hand it would have been about $18,910. The cost of cleaning per 1,000 square yards has been reduced from 18.6 to 15.8 cents. The machines were obtained from the Sanitary Street Cleaning Company of Washington at $6.25 per month for a year, after which period they passed into the possession of the District. The company kept them in good repair during the rental period.

Plumbing in the Flat-Iron Building, New York.

The Flat-Iron Building is so called from the peculiar shape of the lot it occupies at Broadway, Fifth Avenue and Twenty-second Street, New York. It covers all the space enclosed by their intersections, which is in the shape of a triangle with base and perpendicular of 86 and 171 feet. Each of the corners is rounded off to a radius of 8 or 10 feet, and the prominence of its location and the peculiar appearance of the wedge-shaped walls rising nearly 285 feet above the pavement in an isolated position, have given it much notoriety. It is a modern steel-cage office building and a perspective view and structural details of the framework were published in The Engineering Record of March 29. The plumbing requirements are the same as for other metropolitan office buildings, but as rentals in it will be very valuable pains were taken to reduce the space occupied by the water and sewage installation, and to simplify it, and some special features and details were introduced. This work was designed and executed by the same parties who did the plumbing in the Maiden Lane Building, which was illustrated in The Engineering Record of September 6, and conformed to the system of water distribution adopted there in general, but varied from it in arrangement and detail as well as in some essential features which will be described here.



PLAN OF COLD WATER DISTRIBUTION AND ARRANGEMENT OF LEADERS IN THE ATTIC.

In general, water for the upper stories is supplied downwards under tank pressure from distribution mains in the attic, and for the lower stories is supplied upwards under street pressure from a distribution main on the basement ceiling. These two systems are not cross connected and are both entirely independent of the fire system, differing in these respects and in the absence of distribution drums and individual waste and emptying pipes for the separate lines, from most office building systems in this city. Water is received from the street main through a 3-inch connection which is immediately enlarged to 4 inches and has two 3-inch branches, each of which is separately metered and valved to a 4-inch pipe discharging through two Ford ball cocks to the 4,000-gallon steel suction tank in the cellar.

From the suction tank a 5-inch pipe is run with branches to four Fairbanks pumps and is by-passed so that the supply can be taken direct from the meters without passing through the tank. One pump is for emergency use and has two 4-inch branches from its discharge; one of them connects with the stand pipe for fire purposes, exclusively, and the other discharges into the sewer from the rain water leader just beyond its main trap. It is used in connection with a special suction from the catch basin to empty it in case the automatic ejector is out of service. The other three pumps each have two 3-inch branches from their outlets. One of each pair is connected to the tank supply riser and the other to the boiler feed main. This arrangement makes the three pumps interchangeable and provides one for continuous house service, one for continuous boiler service and leaves the third in reserve. Each is controlled by a Utility governor connected to the steam valve so as to open and close it when the level of the water in the tank falls or rises beyond fixed limits.

The stand pipe has a 2½-inch outlet and 50 feet of hose in the corridor of every story and on the roof. It is exceptional in that it has no connection whatever with the house supply or boiler systems but has a branch to the street which terminates above the sidewalk in a Siamese connection for fire engines so that they can augment the supply or pressure if necessary. Check valves are set at the pump and inside the Siamese connection to prevent the escape of pressure into the street or through the pump.

The house pumps deliver through a 3-inch riser and four Ford ball cocks into a 4,000-gallon attic tank from which there are two 3-inch outlets, one to supply water for flushing the water closets and the other to supply all other fixtures above the second story. A separate supply is run to the hot water tank in the cellar and horizontal mains are run on the attic floor with vertical pipes down to the different groups of fixtures, each line being valved at the top and terminating at the bottom in the third story with a reverse bend which forms an air chamber about 2 feet high. These lines can be emptied through the lowest fixtures but are not connected or valved at the bottoms. The great height of the building produces a maximum tank pressure of nearly 150 pounds in the cellar and this is regulated to some extent by throttling the valves controlling the wash basins and slop sinks. Each of the two pipes supplying the flushing water for the water closets in the men's and women's toilet rooms has a pressure reducing valve set in a short vertical section of the pipe, offset from the main line to facilitate connections as indicated in the general diagram.

The cold water is supplied to the Mott heater with automatic steam regulating device, through a 2-inch pipe and the hot water is delivered from it through a single 1½-inch vertical pipe which has a branch at every story connecting with the different slop sinks, and the wash basins in the men's toilet room. As the riser is about 300 feet high provision for temperature expansion and contraction is made between floors by four equi-distant horizontal loops about 2 feet long and the pipe is rigidly supported in the middle of each section between loops. This is intended to limit the vertical displacement at any fixture to ⅛ inch. The diameter of the pipe decreases upwards and at the top it makes a return bend and runs parallel with itself back to the hot water tank where it is connected with the inlet and serves for return circulation. The upper end of the riser is vented over the attic tank and the return leg has four expansion loops corresponding to those on the riser, and has at the bottom a loosely swinging angle check valve set to stand open when no water is being drawn from the riser. Circulation in the return leg is promoted by taking from it branches to supply the fixtures in the women's toilet room, the barber shop and in the engineer's toilet room. A supply is taken from the basement main between the meter and the suction tank and run on the basement ceiling to connect with branches to all cold water fixtures below the third story.

All water, soil, waste and vent pipes are screw jointed galvanized iron except the short connecting lead waste branches and the exposed pipes at public fixtures which are of brass, nickel plated. All water pipes, brass work and valves below the seventh floor are extra heavy. All soil, waste and vent pipes were tested by being filled with water to above the roof level. All exposed pipes in the basement and cellar and all hot water pipes are jacketed with woolen felt, lap jointed, covered with insulated paper, waterproofed and enclosed in painted canvas. The hot and cold water risers are run behind the fireproofing of the columns and partitions and are supported by clamp collars, made in two flanged halves bolted tightly together to grip the pipe firmly just below a coupling sleeve, and having their extended flanges resting across the tops of the floorbeams. The 6 and 8-inch risers for the fire line and the leader system are supported at every floor by U-shaped collars with flanges bent out at right angles at both ends. The depth of the U is nearly as great as the diameter of the pipe and the flanges are drawn up close to the edge of a floorbeam by horizontal bolts with nuts on the flanges and hooks which engage the opposite edges of the upper flanges of the floorbeams. All valves have direction arrows on their hand wheels and are tested to 250 pounds pressure. Up to 2½ inches the body is of brass, above that diameter it is of iron.

The roof tank is seated in a steel safe pan 4 inches deep, and has a wooden cover with hinged doors. It is made of ¼-inch steel and has a central partition dividing it into independent parts for the flushing service and for the general supply. Each portion of the tank is supplied through two 2-inch Ford ball cocks, and has a single 3-inch outlet, both outlets being connected outside the tank with a by-pass and valve which is usually closed. The centers of the 5-inch overflow pipes are set 3½ inches below the upper edges of the tanks, and they discharge into the top of the 8-inch leader pipe. There are no floats nor high and low water alarms or height gauge, but there is a pressure pipe to the pump governors and a ¾-inch tell tale pipe emptying in the engineer's sink. The tell tale, the pump riser and the down supply to the hot water tank are located accessibly in a pipe shaft reaching from cellar to attic and containing also the 6-inch fire line, the 8-inch leader pipe and steam, vent and soil pipes.

The supply from the street main is through a 4-inch cast iron pipe outside the building where it is buried in the earth. This connects with a screwed steel pipe which enters through an arched opening in the basement wall where the main sewer emerges. Inside the wall the pipe has two branches to 3-inch Worthington meters seated on a solid brick pier. From their outlets 3-inch branches are carried down to the floor at both ends of the pier and unite in a 4-inch main which passes under the floor to the suction tank. By this arrangement either meter can be thrown out of service without interfering with the supply.

The toilet rooms are on the 11th floor, midway from top to bottom of building; the men's room has 32 water closets, six urinals, two wash basins and a slop sink, the women's has eight water closets and two wash basins. Each

Attic Tank.

other floor has only a urinal and a slop sink, except in the basement where there is an engineer's toilet room with water closet, wash basin and shower bath. Each office floor has about a dozen wash-basins with provision for several additional ones if necessitated by subdivision of rooms or change of partitions. The toilet rooms are wainscoted and paneled with Italian marble and the wash basins, slop sinks and urinals on all floors have marble floor and wall slabs and marble tables with nickel plated legs. The total present number of fixtures includes about 49 water closets, 26 urinals, 20 slop sinks, 2 iron sinks and 275 wash basins.

The flat tiled roof is arranged with a number of summits from which the surface slopes in both directions to shallow copper lined basins in the center of each of which there is an outlet with a 4-inch soldered copper sleeve which connects with a brass ferrule and a sleeve coupling with a vertical branch. The vertical branch discharges through a Y into a collecting pipe which is supported on brick piers on the concrete floor of the attic. This pipe parallels the two long walls of the building and receives ten branches from the roof and nine from the cornice and connects with an 8-inch vertical pipe to the basement which enters the house sewer outside its main trap as shown in the drawings of the attic floor plan and of the meter connections. Just below the roof each pipe has a steam connection to use in thawing it out in case it should be stopped by ice. The drains from the gutter outside the balustrade, have to be made with offsets, as shown in the detail, to clear the roof and cornice girders. They are connected up similarly to those from the roof drains and their feet are accessible from clean outs. All soil and vent pipes are enclosed above the roof with pieces of lead soil pipes ⅛ inch thick. The upper end of the lead pipe projects above the top of the iron pipe and turns down 1 inch inside it. The lower end is soldered to a lead flashing 20 inches or more square.

All soil pipe branches from water closets and slop sinks are run between floor and ceiling and all their horizontal vent pipes are run between the ceiling and floor next above the fixture to the vertical pipe. In the eleventh story toilet rooms the soil and vent lines were set before the walls were plastered or the floors finished, and being arranged for so many fixtures made an attractive appearance on account of their symmetry and regular arrangement. The group of pipes in the center of the floor for the urinals, wash basins and slop sink were completely isolated from the rest which were arranged along the walls and are concealed between the marble back slabs of the urinal stalls. The waste and water supply pipes are run from the fixtures to the risers under the floor and the vent pipe is run to its riser above the ceiling. In every story extra openings are provided in the soil and waste lines and are plugged so as to allow for future connections if necessary. Corresponding plugged outlets are left in the hot and cold water lines.

The areas and cellar floor are provided with cast brass cesspools, having bell traps and 9x9-inch hinged strainer covers. These discharge to the ejector tank which also receives the soil and waste from the engineer's toilet room and the drip sink, etc. The cellar excavation was made in rock and considerable ground water was encountered which is collected in open jointed glazed tile drains which lead to a number of small brick catch basins below the cellar floor. These basins all discharge into a larger central basin about 30 inches in diameter and 5 feet deep which normally overflows to the ejector tank. The contents of the main catch basin can be discharged by the emergency pump into the leader waste outside its trap, but normally they overflow into the ejector tank and are automatically discharged into the same pipe between the sewer and the pump.

Messrs. D. H. Burnham & Company, Chicago, are the architects of the building and the George A. Fuller Company is the general contractor. The plumbing work was done by the Wells & Newton Company, Mr. John Mooring, foreman.

Tests of the Glasgow Tramways Engines.

In 1899, as may be remembered, The Engineering Record made a brief reference to the excitement that was aroused in Great Britain when it was recommended that the contract for the steam engine equipment for the new power-house of the Glasgow tramways be placed with an American firm and on a design based on American practice in power machinery for street railway service. The controversy over those transactions is now again brought to mind by a recently published report of tests of the completed engines, which by their extraordinary performance go far toward justifying the American design. It will first, however, be well to review briefly the early history of the subject.

At the initial letting, four firms tendered bids, and on the advice of the consulting engineer, Mr. H. F. Parshall, M. Inst. C. E., the Edward P. Allis Company, of Milwaukee, now of the Allis-Chalmers Company, was given the contract. When the matter came up for confirmation, however, so strong was the feeling that the work should not go out of the country, that finally it was given to Messrs. John Musgrave & Sons, Limited, of Bolton, Eng., on a specification similar to that under which the American bid was made. It was then found that they could not promise delivery within the required time, and eventually the work was divided between them and the Allis Company, as regards the large engines, and another contract was awarded to Messrs. D. Stewart & Company, of Glasgow, for two smaller engines.

Four main engines, each of 4,000 indicated horse-power at normal load, and two engines of 750 horse-power, were required. With regard to the main engines great surprise was manifested at the dimensions recommended by Mr. Parshall, and with which the Allis engine accorded, one of the bidders asserting that their design had only about 70 per cent. of the weight of the Allis engine. The Musgrave engines were modified, however, according to the American ideas, including enlarged bearings to reduce friction by lessened bearing pressure. Each engine has one high-pressure cylinder, 42 inches in diameter and two low-pressure cylinders, each 62 inches in diameter; the common stroke is 60 inches. The steam pressure is 150 pounds and the speed 75 revolutions per minute.

The tests were conducted by Prof. Barr, of Glasgow University, and are reported in "Engineering." He found that the Allis engines operated under a mechanical efficiency of 96 per cent., and at the remarkable steam consumption of 12.2 pounds of steam per indicated horse-power per hour. Incidentally it may be mentioned they were delivered a month before the specified time. They were guaranteed to work with 14 pounds of steam per indicated horse-power, while the Musgrave engines were restricted to 14.5 pounds per indicated horse-power hour. These engines, however, also exceeded their guarantee, using 13.4 pounds of steam per indicated horse-power hour in one case, and 13.2 pounds in the other; the steam consumption per brake-horse-power per hour was 13.9 and 13.6 pounds. The combined efficiency of both engine and generator was 93 per cent. and the mechanical efficiency of the engines, 96 and 97 per cent.

The Stewart engines are of the two-cylinder vertical cross-compound type and drive 500-kilowatt direct-current dynamos. They have a normal working load of 800 horse-power, but are capable of working continuously at 1,000 horse-power and for short periods at 1,200 horse-power. The cylinders are 22 and 44 inches in diameter by 42 inches stroke and the speed 90 revolutions per minute. The guaranteed steam consumption was 14.5 pounds per brake-horse-power hour and the combined efficiency, 92 per cent. According to two trials early in the year, one engine used 14.2 pounds of steam per indicated horse-power per hour, and the other 14.8 pounds. The combined efficiencies were 88.3 and 88.5 per cent. and the mechanical efficiencies of the engines, taking the efficiency of the dynamo as 94.6 per cent., were 93.4 and 93.7, respectively.

The By-Product Coke Oven continues to grow in favor in the United States, according to figures collected by Mr. Edward D. Parker. There were 1,165 such ovens in use at the close of 1901 and 1,553 under construction. The average production was a little over 1,000 tons per oven, about three times that of the beehive ovens during the same period. A little over half of the number in operation were run in connection with iron and steel plants, and a larger proportion of those under construction will be so operated. The total output of these ovens during 1901 is valued as follows: Coke, \$2,894,077; tar, sulphate of ammonia and ammoniacal liquor, \$1,029,876. The market for the by-products is stated to be good, and to show no signs of over-supply, a condition that opponents of this class of oven assert will surely follow their introduction.

The Filter Beds for purifying the water supply of Nuneaton, Eng., were described by Mr. J. S. Pickering, the waterworks engineer, at the meeting of the Association of Municipal and County Engineers held at that place last fall, substantially as follows: The water when pumped from the wells contains iron in solution, which oxidizes on exposure and produces a turbid appearance. The four filters by which this iron is removed have each an area of 200 square yards. They are composed of a depth of 3 feet of sand, under which is laid a 12-inch layer of granite chippings, the whole being supported on a false floor composed of special perforated tiles. The tiles are 16 inches square, and are laid loosely on rows of bricks so formed as to thoroughly drain the beds. The outlets from the beds are movable iron arms, which can be raised and lowered at will in order to regulate the head of water on the filters. When a filter requires cleansing the filtered water from another bed can be delivered into the bottom and utilized for upward washing, the dirt being discharged with the water through a swivel elbow pipe fixed immediately below the surface of the sand. The water from the filter-beds is conveyed through a 15-inch main, by gravitation, to the covered service reservoirs, which have a capacity of 800,000 imperial gallons. The walls of the reservoirs are built of brickwork and the floors are of concrete. The roof consists of a series of brick arches springing from brick arched walls. The floors and walls are rendered ¾ inch thick with cement mortar.

Insulators for Long-Distance Power Transmission Lines.

The following note relating to insulators for electric power transmission lines is taken from an interesting paper on the problems and difficulties of the transmission of power long distances, read by Dr. F. A. C. Perrine before the Massachusetts Institute of Technology and printed in the "Technology Quarterly" for June.

For potentials up to about 25,000 volts, where an insulator of 7-inch diameter is sufficient, there seems not much reason for the employment of anything except glass, unless the lines reach a size above half an inch in diameter, when its strength is deficient. For these lower potentials and lighter lines the good properties of glass are easily summarized. In the first place, it is cheaper by far; while not so strong as porcelain, it is, as has already been said, sufficiently strong for the purpose; its inspection is easier and surer, since it requires only a visual examination and a few taps of a hammer to ascertain its soundness in place of the tedious hign potential test necessary in the examination of porcelain. But having said this much, all has been said that is possible in favor of glass.

It is not true that glass is a better insulator than sound porcelain, nor is its surfaee so good in damp weather against surface leakage. The mechanical strength does not equal one-half that of porcelain, as has been proved by a long series of mechanical tests performed by dropping a steel ball from a height upon insulators of the two materials; temperature also affects it much more than porcelain and it is often found to crack simply from the effect of extreme changes of temperature.

The insulators for high voltage lines must be very large, for the reason that with a striking distance through the air of from 4 to 6 inches, great gaps must be provided in the path of the current. But above all a great creeping distance is essential. Insulators that are a perfect protection in the hardest rains fail utterly in clear weather when covered by smoke and soot, which allow small amounts of currents to escape and char away the pins or cross-arms. The compound insulator is very attractive, for the reason that it is easier and cheaper to make and handle two or three small parts rather than one large one, and in some cases the additional advantage has been sought of securing the good properties of both glass and porcelain by making parts of an insulator of each; but there is both a theoretical and practical fallacy in this type of design. In the first place, no dielectric is so strong as one entirely homogeneous. As the stress is passed from glass to porcelain, or vice versa, at the two surfaces the stress piles up as it were, and it is better if one believes in glass to rely upon it; or, on the other hand, to show faith in the porcelain used by employing it entirely.

From the pure standpoint of practice the insulator which must be cemented together is troublesome. The shrinking of the mastic leaves voids and produces strains; if cement be used, its slowness in hardening delays the work and requires large areas for setting out to harden any considerable number of insulators. The one other mastic in use is molten sulphur, which, while better as a mastic than cement, is still more liable to crack the insulators while they are being joined, and finally when exposed to light and air, frequently decomposes on the surface, producing sulphuric acid; and, finally, when current creeps over its surface following the acid, perhaps, catches fire and often results in the rupture and fall of the insulator. The insulator which will be entirely satisfactory for this use has not yet been found, but the diligent search made for it by some of our best engineers is resulting in its definition and will probably soon result in its production, not as an inspiration for a patent, but as a careful engineering conception.

Trade Publications.

A number of additions have recently been made to the useful series of bulletins issued by the Bullock Electric Mfg. Co., Cincinnati, as follows: No. 1,006, railway generators of 100 to 2,500 kilowatts capacity; No. 1,007, variable speed motors, a discussion of the different methods of securing variable speeds and of the motors best suited for various classes of machine tools; No. 1,009, multiple voltage, a full explanation of the Bullock system of control for variable-speed motors; No. 1,010, the electrical equipment of the shipyard of the Fore River Ship & Engine Co.; No. 1,014, Bullock motors applied to cold storage plants; No. 19, alternating current engineering, an account of its development. All these pamphlets are well illustrated.

The highly developed hydraulic ram known as the Foster impact engine, an improvement of the Rife ram, is described in a circular of the Power Specialty Co., 126 Liberty St., New York. It is guaranteed to have 60 to 80 per cent. efficiency, to work under a head of 2 feet, and to pump clear water from one source with a muddy supply from another without mixing the two.

The S. K. C. inductor alternator is described in Bulletin 128 of the Stanley Electric Mfg. Co., Pittsfield, Mass. Bulletin 123, previously published, explains the electrical technicalities of this machine, while the new pamphlet is a general explanation of its advantages and construction. It is well illustrated.

The Chapman Valve Mfg. Co., Indian Orchard, Mass., has issued a special catalogue of its electrically operated valves for steam and water power plants, water and sewerage systems, dry-docks and other works large enough to use power-driven gates. The catalogue is profusely illustrated.

Perrin, Seamans & Co., 57 Oliver St., Boston, have just issued a new catalogue showing their large line of tools and supplies for sewer, water-works and electric railway construction. The book contains over 300 illustrations, most of which are accompanied by short descriptive articles. As a reference book for contractors this catalogue will doubtless prove of much value.

The American Graphite Co., Cleveland, has issued a preliminary circular concerning a new paint for wood and metal called "Graphault." It is not claimed to be quick-drying, the merits claimed being elasticity and permanence.

The development of the Jeanesville pump is sketched in a 20-page pamphlet forming advance sheets of the general catalogue of the Jeanesville, Pa., Iron Works Co. The leading types now made are explained, with illustrations and tables of dimensions, and there are a number of illustrations of typical arrangements of pumping plants for underground stations. Other advance sheets describe the jet and surface condensers made by the company.

The Reynold silent chain gear, described in a new bulletin of the Link-Belt Engineering Co., Philadelphia, consists of a link chain made with teeth in six pitches and many widths, and cut sprocket wheels with teeth having straight sides. Every tooth in mesh in this gear is doing useful work, and the effect of wear in the chain is to change the point of contact of the teeth of the wheel and chain and not to decrease the number of teeth in contact. Numerous applications of the gear to motor-driven tools are illustrated.

The Ridgway system of belt conveyors is explained in a well-illustrated pamphlet issued by the John A. Mead Mfg. Co., 11 Broadway, New York. In this system there is a special belt designed to curve readily into a trough section, and an arrangement of idlers having a large horizontal pulley and smaller troughing pulleys some inches back of the former in order to curve the belt without any tendency to produce an angle bend.

The General Electric Company's latest bulletins are the following: No. 4,295, oil switches; No. 4,296, a switch for a system of remote control; No. 4,297, high-voltage, type H transformers; No. 4,298, the Thomson high torque induction meter. All are fully illustrated, and the last-named contains an interesting description of a new measuring device on which the attention of some eminent electricians has been long directed. The company has also issued a special volume of excellent engravings of electric hoists, covering all types for which steam has been used hitherto. The advantages of such apparatus have been recognized for many stationary purposes, but its usefulness in erecting buildings and other branches of contracting has not yet been appreciated.

A folder containing some illustrations of belt conveyors in large salt works has just been prepared by the Robins Conveying Belt Co., 21 Park Row, New York. These installations are particularly noteworthy, as the action of salt on most conveying apparatus is very destructive.

The Laidlaw-Dunn-Gordon Co., Cincinnati, has prepared a 120-page catalogue of air and gas compressors which, in addition to descriptions of the company's machines, contains a chapter on two-stage and multi-stage compression and many pages of useful tables for users of compressed air, some of them covering subjects on which it is hard to find tabular data, such as the sizes of air-driven pumps for different conditions, the air required for different numbers of drills at various altitudes, and the best ratios of steam and air cylinders to satisfy various requirements. The company has also issued a new catalogue of deep-well pumping machinery, and a bulletin on small two-stage straight-line compressors.

The John A. Roebling's Sons Co., Trenton, N. J., has published in an attractive morocco binding a little pamphlet of directions concerning the proper form in which to order wire rope and wire, so as to have the shipment made without delay.

The Crane Co., of Chicago, has issued a 161-page catalogue of valves, gates, specials, boiler accessories and other supplies for the steam fitter and plumber. It is a very complete book of convenient size and well bound. Its contents are so varied that a list of them would require more space than is available here. The sections on high-pressure piping deserve special mention.

The Goulds Mfg. Co., Seneca Falls, N. Y., has published a handsome book on power pumps for every class of service, from the tank pump in houses to the powerful machines for pulp mills and mine drainage.

A concrete catechism has been published by T. L. Smith, 134 Tenth St., Milwaukee, Wis., which ought to be in the hands—or heads—of all concrete foremen. It tells in the simplest language what is essential to securing a good product.

The Ashton Valve Co., 271 Franklin St., Boston, has issued a folder describing a new blow-off valve. This has a split piston fitting a cylindrical seat. When screwed down the piston is wedged tight in the chamber, and when screwed up the wedge is drawn up first so as to allow the piston to rise freely out of the way of the discharge.

Personal and Obituary Notes.

Mr. James A. Omberg, Jr., has been appointed city engineer of Memphis, Tenn., succeeding Mr. A. T. Bell, resigned.

Mr. A. F. Doremus, state engineer of Utah, and Mr. F. C. Kelsey, former city engineer of Salt Lake City, have formed a partnership, with offices in the McCormick Block, Salt Lake City, for the construction of water-works and irrigation works.

Mr. George W. Birdsall for 32 years with the water department of New York City and for 20 years its chief engineer, has been appointed consulting engineer of the department, which is now the Department of Water Supply, Gas and Electricity. He is succeeded as chief engineer by Mr. Nicholas S. Hill, Jr. Mr. Hill is probably best known as engineer for the Electrical Subway Commission of Baltimore, and later, in 1897, as chief engineer of the Baltimore Water Department. Of late he has been conducting a private practice.

Mr. J. F. Wallace, past president of the American Society of Civil Engineers, for many years chief engineer of the Illinois Central Railroad, and since January, 1901, assistant general manager of that road, has been appointed general manager with headquarters in Chicago. Mr. W. J. Harahan, Assoc. M. Am. Soc. C. E., chief engineer of the road, succeeds him as assistant general manager, and Mr. H. U. Wallace, superintendent of the Freeport division of the Illinois Central Railroad, becomes chief engineer, succeeding Mr. Harahan. Mr. J. F. Wallace, who, by his steady advancement into executive positions has frequently been held as an exponent of the growing practice of installing the engineer into positions of business management, has filled a succession of responsible railway engagements since 1879, when he was elected chief engineer of the Burlington, Monmouth & Illinois Railway. Mr. Harahan began his railway career in 1881 as messenger and clerk in the superintendent's office of the Louisville & Nashville Railroad, and in 1899 was appointed engineer of maintenance of way on the Chesapeake & Ohio Railroad, from 1890 to 1892 was in charge of structures on the Baltimore & Ohio Southwestern, and in 1892 entered the service of the Illinois Central Railroad. Mr. H. U. Wallace entered upon railroad work in 1888, and began with the Illinois Central in 1894, serving successively as assistant engineer, roadmaster, assistant superintendent and superintendent.

The following candidates for the various grades of membership in the American Society of Civil Engineers were announced elected October 1. Members: Percy Allan, engineer, Pyrmont bridge, Sydney, New South Wales, Australia; G. J. Bell, county surveyor and bridge master, Carlisle, Eng.; G. H. Binkley, engineer and manager, Railway Dept., Kohler Bros., Chicago; George Bowers, city engineer, Lowell, Mass.; F. E. Crane, city engineer, Amsterdam, N. Y.; Harvey Farrington, Croton-on-Hudson, N. Y.; J. W. Kendrick, city engineer, Birmingham, Ala.; C. H. Kluegel, chief engineer, Oahu Railway & Land Co., Honolulu, H. I.; T. H. Mather, chief engineer for C. D. Beebe, Syracuse, N. Y.; F. B. Sanborn, prof. Civil Engineering, Tufts College, Mass.; F. E. Schall, bridge engineer, Lehigh Valley R. R., South Bethlehem, Pa.; G. W. Sublette, city engineer, Minneapolis, Minn.; Fred Thompson, civil engineer, U. S. N., Norfolk, Va.; C. H. West, chief engineer, Mississippi Levee District, Greenville, Miss.; R. C. Young, chief engineer, Des Moines, Iowa Falls & Northern Ry., Iowa Falls, Ia. Associate members: Ralph Albree, partner with Chester B. Albree, Allegheny, Pa.; R. W. Carter, assistant engineer, Missouri Valley Bridge & Iron Works, Leavenworth, Kan.; A. A. Conger, assistant engineer, Michigan Lake Superior Power Co., Sault Ste. Marie, Mich.; D. T. Corning, assistant engineer, Troy Water-Works Extension, Tomhannock, N. Y.; W. R. Craig, engineer, maintenance of way, Pittsburg, Shawmut & Northern R. R., St. Marys, Pa.; F. O. Dufour, assistant professor, Civil Engineering, Univ. of Cincinnati, Cincinnati; G. H. Fenkell, civil engineer to Comm. of Water Works, Erie, Pa.; F. L. Ford, city engineer, Hartford, Conn.; R. E. Griswold, assistant general agent, New Trinidad Lake Asphalt Co., Port of Spain, Trinidad, B. W. I.; L. W. Hall, chief draftsman, U. S. Engineer office, Tuscaloosa, Ala.; F. E. Lane, resident engineer, Atlantic Ave. Improvement, Brooklyn, N. Y.; N. B. Livermore, private practice, San Francisco; D. A. MacCrea, division engineer, Choctaw, Oklahoma & Gulf R. R., Guthrie, O. T.; L. H. Mattair, sanitary engineer, Matanzas, Cuba; H. F. Nichols, manager, James Hill & Sons, Adelaide, So. Australia; E. P. Ramsay, assistant engineer, Rapid Transit R. R. Comm., New York; C. L. E. Schenk, contracting engineer, Tate, Jones & Co., Pittsburg, Pa.; W. F. Steffens, with New York Central & Hudson River R. R., New York City; W. A. Tyrrell, engineer for E. P. Maule, Jr., St. Louis, Mo.

Attention to Water Gates between the high and low-service gates of the Brooklyn, N. Y., water-works has resulted in an important reduction in the high-service pumping. Mr. I. M. De Varona, chief engineer of the department, refers particularly to these results in a recent report as an illustration of the economy attainable by an intelligent study of water distribution and a careful adjustment of the boundary between districts having supplies under different pressures.

Traction on Highways was the subject of a long report to the Engineering Section of the recent convention of the British Association. The general conclusions are that the resistance to traction comes from three independent sources, axle friction, rolling resistance and grade resistance. The last is known to be 20 pounds per ton for a 1 per cent. grade. Axle friction has nothing to do with the surface of the road, and varies with the material of the parts and the lubricant. It is nearly independent of the velocity, but varies inversely as the load. With good lubrication, it is about 2 per cent. of the axle load with light carriages and 1½ per cent. with heavy carts. The tractive force required to overcome axle friction is about 3 to 3½ pounds per ton of axle load for ordinary wagons. The rolling resistance varies with the diameter of the wheel, the width of the tire, the speed, the presence or absence of springs and the nature of the road surface. The rolling resistance increases with the velocity owing to the effect of the shocks or concussions produced by the irregularities of the road surface. It requires from two to eight times as much force to start a vehicle as to keep it in motion at 2 or 3 miles an hour. The committee credits Prof. I. O. Baker with furnishing much valuable experimental data.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see page xv, xvii, xviii and xxvii.

WATER.

Providence, R. I.—Local press reports state that a 12-in. main is to be run through Park Ave., replacing smaller pipe for the supply of water to the western part of the town of Cranston.

Newport, R. I.—See "Government Work."

Troy, N. Y.—Bids are wanted Oct. 15 for building 1 gate house with fixtures and appurtenances and laying approximately 120 ft. of 20-in. cast-iron pipe. John Phelan, Comr. of Pub. Wks.

Baldwins, L. I., N. Y.—The contract for constructing the Millburn pumping plant has been awarded to Henry R. Worthington for $51,000, and the contract for 2 boilers to Edwin Burhorn, of Brooklyn, for $11,400.

Pittsburg, Pa.—The Pennsylvania Water Co. is stated to have awarded the contract for constructing a storage reservoir of 6,000,000 gal. capacity on a high point near Wilmerding to the T. A. Gillespie Co., Pittsburg.

Canajoharie, N. Y.—The Fultonville Water Co., of Canajoharie, has been incorporated, with a capital of $30,000. Directors: David Gring, Newport, Pa.; Mark E. and S. S. Johnson, of Canajoharie.

Troy, Pa.—Local press reports state that the Boro. Council has decided to accept the offer of the Troy Water Co. to sell its plant to the Boro. for $25,000, with the reservation of the reservoir, two wells near the power house, windmill and one line of pipe of minor importance.

Erie, Pa.—The Bd. of Water Comrs. is reported to have engaged Geo. H. Fenkell, of Detroit, Mich., to make surveys for the extension of the intake water pipe across the Peninsula and into the lake from where the city water supply is to be pumped.

Washington, D. C.—Bids will be received by the Comrs. D. C. until Oct. 18 for furnishing cast-iron specials, as advertised in The Engineering Record.

McRae, Ga.—Moore & McCrary, Engrs., of Atlanta, Ga., have the contract for furnishing labor and material necessary to complete the water works, their bid at $15,000 being the only one received Sept. 23.

Lynchburg, Va.—City Surveyor M. H. Garland is making surveys of the route for a line of pipe with which it is proposed to supply water from Pedlar River in Amherst Co., by means of gravity.

Berryville, Va.—D. G. Adelsberger, of Baltimore, has prepared plans for the improvement of the water works, which call for a new 600,000-gal. reservoir at Mountain Springs and a new 2,500,000-gal. reservoir on the west side of town.

Graham, Va.—Town Recorder O. A. Metcalfe writes that the contract for constructing water works was let Sept. 29 to Fred. Minshall, of Greenwood, S. C., on his bid of $17,300, work to begin at once. Capacity of plant will be half a million gallons per day.

Lima, O.—An ordinance before the Council provides for the issue of $150,000 bonds for the construction of a storage reservoir.

Springfield, Ill.—The Council has adopted an ordinance providing for the placing of water meters (to be furnished by the city) on all service pipes in the city, not later than Jan. 1, 1904.

Sweet Springs, Mo.—Water and electric light bonds to the amount of $12,000 are reported to have been sold.

Webster Groves, Mo.—At the special election held Sept. 30, it was voted to issue bonds not to exceed $50,000, for installation of a system of water mains within the city limits.

Chicago, Ill.—The lowest bid received for constructing the foundation for the superstructure, pumps and intake for 39th St. pumping station is stated to have been from John P. Agnew at $215,000.

Colby, Wis.—Bids will be received by the Mayor and City Council until Oct. 14 for furnishing machinery, apparatus, material and supplies for water works and electric light plant, as advertised in The Engineering Record.

East Dundee, Ill.—Bids are wanted Oct. 21 for constructing a standpipe and engine and pump, as advertised in The Engineering Record.

Elgin, Ill.—The City Council has passed an ordinance providing for the issue of $64,000 bonds for the purpose of changing the supply of the water works system from Fox River to artesian wells. Wm. F. Sylla, City Clk.

Kirkwood, Mo.—The contract for constructing water mains is reported to have been let to Geo. Stuckey, for about $30,000.

Grossdale, Ill.—The contract for installing 9 miles of pipe for the water works system is reported to have been let to John M. Healy, of Chicago, for $51,200.

Howell, Ind.—The Town Bd. has granted a franchise for water works to G. H. Williams and E. J. Ellis, both of the Evansville Gas & Electric Light Co. Estimated cost of plant to be installed, $32,000.

Armada, Mich.—Bonds to the amount of $4,000 have been voted for water works.

Des Moines, Ia.—Local press reports state that the Des Moines Water Co. will lay 8 miles of new mains this fall.

Slater, Ia.—Bids are wanted Oct. 10 for drilling and completing a well.

Mt. Clemens, Mich.—Bids are wanted Oct. 17 for a 3,000,000-gal. pumping engine. Henry C. Benton, City Clk.

St. Louis, Mo.—Bids are wanted Oct. 11 for a high pressure system of water pipes for fire protection at the World's Fair, as advertised in The Engineering Record.

Abingdon, Ill.—Hydraulic Engr. Geo. Cadogan Morgan, Royal Insurance Bldg., Chicago, Ill., writes that water works contracts (bids opened Sept. 23) have been awarded as follows: To Stilwell-Bierce & Smith-Vaile Co., Chicago, deep pumping engine and cylinder, $776; to Washington Steam Boiler Wks., Chicago, steel work of water tower, $1,496; to J. A. Miller & Bro., Chicago, cornice, etc., for $156; to Jones & Laughlin, Chicago, eye beams, for $48.50; all other materials in detail and masonry and brick work by local contractors; the boiler and heater bids under advisement. About 5 miles of water mains to be let late this fall or early in the winter.

Tryon, Okla. Ter.—The Tryon Townsite & Water Co., of Tryon, has been granted a charter for five years, with a capital stock of $2,500. The incorporators are: A. M. Jines, of Ochiltree, Tex.; R. B. Queen, of Guymon; H. L. Huber, and others, of Tryon.

Quanah, Tex.—Local press reports state that water works bonds have been voted and a system is about to be constructed.

Marshall, Tex.—The City Council has passed an ordinance authorizing the issue of $15,000 bonds for the betterment of the water works.

Gueydan, La.—Local press reports state that the Comrs. of Gueydan Drainage Dist. have accepted the report of Engr. Arsene Perrilliat, locating all main canals and branches. The canals will be about 25 miles long, and from 25 to 40 ft. wide at the bottom, with a depth of from 2 to 4½ ft. It is stated that bids for said work will be received until Nov. 4, the work to consist of about 500,000 cu. yds. of mud free from stumps, and about 43,000 cu. yds. to be done with dredge or scrapers.

Biloxi, Miss.—Engrs. Kirkpatrick & Johnson, of Jackson, Miss., write that contracts for furnishing pipe, etc., (bids opened Sept. 16) have been awarded as follows: 7 miles of 8 to 4-in. cast-iron pipe to U. S. Cast-Iron Pipe & Fdy. Co., Chattanooga, at $32 to $34 per ton; hydrants and valves to R. D. Wood & Co., Philadelphia; pipe laying to Thos. Wagner, of Mobile, Ala., at 11 cts., 12 cts. and 13½ cts., respectively, for 4, 6 and 8-in. pipe; connecting service pipes, to Martin Haas, Biloxi, at $2.35 each.

Belzona, Miss.—The Consumers' Light & Water Co., of Belzona, has been incorporated with a capital of $100,000. Incorporators: Stephen Castleman, Jonas H. Levy and Sam Hyman.

Beaumont, Tex.—The Iowa Irrigation Co., of Beaumont, has been incorporated, with a capital of $200,000. Purpose, to construct, maintain and operate dams, reservoirs, lakes, wells, canals, ditches, flumes, feeders, laterals, sluices and other necessary appurtenances for the purpose of irrigation, navigation, mining, milling, stock raising and city water works, in the Counties of Newton, Jasper and Orange. Incorporated by C. P. Bratuober, of Waterloo, Ia.; W. A. Dugane, of Cedar Falls; H. W. Potter, of Beaumont, and others.

Morgantown, Ky.—The contract for putting in a water works plant for this city is reported to have been awarded to the Howe Engine Co., of Indianapolis, for $9,000.

Searcy, Ark.—Owen Ford, of St. Louis, Mo., is reported to have prepared estimates for a water system; the issue of bonds for said improvement is under consideration.

Diamond, La.—The Doullut Canal Co. has been chartered with a capital of $40,000.

Duncan, Ind. Ter.—The City Council is stated to have granted to Mr. Daube a franchise to put in water works.

Houston, Tex.—The City Council has adopted a resolution notifying the Houston Water Co. that at the expiration of its present franchise Nov., 1903, there would be no renewal and asking it to fix a price on the property to the city; the resolution provides that in case the company does not comply with the demand to fix a reasonable price the city is to proceed with the building of a new plant.

Elma, Wash.—This city has decided to sink an artesian well to a depth of 500 ft. for the purpose of increasing the city water supply. F. E. Tompkins, City Clk.

San Pedro, Cal.—The Bd. of City Trus. has authorized City Attorney Karr to confer with the officers of the Seaside Water Co. and formulate a franchise for furnishing water and lights that will meet the requirements of the city and be satisfactory to both parties.

San Bernardino, Cal.—City Engr. Rasor has submitted to the Bd. of City Trustees the following estimates of the cost of acquiring possession of and completing a municipal water system: Cost of Hubbard water and laying pipe line from Lord gate to reservoir, $67,000; new 10-in. main, from reservoir to city, enlarging reservoir and complete piping of the city, $95,832; high-grade pumping plant and 3 deep wells on "ant hill" tract, including twenty-two acres of land and piping, supplementary supply to connect with city system, $67,112; cost of same plant on Baldridge tract, including purchase of five acres of land, $65,801; total cost of water system, using "ant hill" plan as the supplementary supply, $229,944; total cost of water system, using Baldridge plan, as the supplementary supply, $228,633.

Meeteetse, Wyo.—A vote will be taken on the proposition to issue $17,000 bonds for the improvement and enlargement of the city water system.

Toledo, Ore.—The Toledo Water & Electric Light Co., of Toledo, has been incorporated with a capital stock of $10,000; incorporators, Thos. Leese, Wm. S. Carth and B. F. Jones.

Mancos, Colo.—Local press reports state that it is proposed to put in a municipal system of water works.

Debeque, Colo.—The question of constructing a system of water works is under consideration.

Aberdeen, Wash.—J. L. Stannard, of Seattle, is said to have been engaged to advise the city authorities concerning water system improvements.

La Junta, Colo.—According to local press reports farmers along the line of the Otero Canal have voted to bond the ditch for $300,000. The city of La Junta will contribute $100,000, making in all $400,000 to be used in the purchase of water rights and the construction of a reservoir.

Sterling, Colo.—Preliminary surveys are stated to have been made for the proposed gravity pressure water system to be built for this city at a probable cost of about $50,000. Water to be brought from Springdale, 5 or 6 miles from the city.

Silver City, N. Mex.—J. A. Harlan is reported to have submitted to the city officials plans for the construction of a breakwater dam for the prevention of floods. Estimated cost, $17,000.

Los Angeles, Cal.—Local press reports state that the Bd. of Water Comrs. recently awarded contracts, amounting to over $150,000, as follows: To U. S. Cast Iron Pipe & Fdy. Co., 3,200 tons of 4 to 30-in. pipe at $38.75 per ton; to Lacy Mfg. Co., Los Angeles, 6,150 ft. of 36-in. sheet-steel pipe, at $3.38 per ft.

Wilbur, Wash.—Bids will be received until Oct. 15 by Julius Lyse, Chmn. Water Wks. Com., for furnishing about 7,200 ft. of 4 to 10-in. pipe, gates, valves and fittings. Bids will be received on steel lap welded converse joint, asphalted pipe, and on wooden stave galvanized bound asphalt pipe. H. S. Bassett, Mayor.

Columbus, Neb.—Press reports state that the Nebraska Central Irrigation Co. has completed arrangements for the construction of a power and irrigation canal, to divert the water of the Loup River from a point near West Point through the canal to an immense storage reservoir, near this city. From the reservoir the water will have a fall of 91 ft., with an outlet into Platte River, and besides furnishing 20,000 H.-P. will also irrigate several thousand acres of land. H. E. Babcock, Pres. Estimated cost, $3,000,000.

Sedro-Woolley, Wash.—H. R. Lamb, of the Skagit Improvement Co., writes that water works are to be constructed by said Co. W. R. Morgan, Engr. in Charge.

Springfield, S. D.—Press reports state that the Council proposes to sink a new artesian well. Cost, $2,500.

Highmore, S. D.—It is stated that steps are being taken to issue bonds for sinking an artesian well.

Alcester, S. D.—Water bonds to the amount of $3,750 are reported to have been voted.

Parker, S. D.—Press reports state that a system of water works is to be constructed.

Raton, N. Mex.—Local press reports state that the Raton Water Works Co. has decided to construct an additional reservoir in Sugarite Canon, and to extend its works at a total cost of $75,000. C. N. Priddy, of Leadville, Colo., is one of the stockholders of the Co. and A. L. Hobbs is Supt.

Golden, Colo.—The following bids are stated to have been received by the City Council for the construction of water works: Mr. Linder, of Golden, $117,000; Holme & Allen, Denver, $114,000, and R. P. McDonald, Denver, $97,000.

Sheridan, Wyo.—The lowest bid recently received for the extension of Shoshone Canal, 8 miles, was from T. F. Frasure, of Garland, at 65 cts. a cu. yd. for solid rock, 40 cts. for loose rock, 25 cts. for gravel and 10 cts. for earth; total, about $18,000.

Cucamonga, Cal.—Articles of incorporation of the Old Settlers' Water Co., of Cucamonga, were filed recently. Capital stock, $33,840. Directors: D. R. Kilbourne, W. J. Kincaid, Thos. Farm and others, of Cucamonga.

Morgan, Utah.—Local press reports state that Weber, Davis, Morgan and Summit Counties propose to construct a reservoir in which to store water for irrigating; the dam, which it is proposed to build, will be about 60 ft. high and 3/5 of a mile long. Estimated cost of reservoir about $500,000.

Sacramento, Cal.—The Bd. of City Trustees has adopted the ordinance providing for the issue of $150,000 bonds for water mains.

Whitney, Idaho.—Articles of incorporation have been filed by the Whitney Reservoir & Ditch Co. Capital, $5,000. Directors: Jos. Moser, Jas. Cutler and others, of Whitney.

Cedar City, Utah.—The City Council is reported to have voted in favor of bonding the city for the construction of a system of water works.

Pueblo, Colo.—The Trus. of the North Side Water Works are reported to have let the contract for a horizontal compound high duty pumping engine, capacity 10,000,000 gal. every 24 hours, to Holme & Allen, of Denver, for $41,000.

Winnipeg, Man.—Rudolph Hering, of New York City, in a recent report on the question of increasing the city water supply, recommends the plan which provides for the sinking of another well about 100 or 200 ft. from the present well, from which a lateral drift or gallery is driven in the rock for a distance of about 200 ft. Estimated cost, $15,130.

SEWERAGE AND SEWAGE DISPOSAL.

Boston, Mass.—Bids will be received by Jas. Donovan, Supt. of Streets, until Oct. 8, for constructing sewerage works in Aldrich St., also until Oct. 10 for constructing sewerage works in Florida St.

Hartford, Conn.—Local press reports state that bids will be received Oct. 15 by the City Engr. for widening the canal below the Franklin Ave. sewer and arching same as recommended by him.

Salem, Mass.—In a communication to the Council Mayor Hurley urges the passage of the $50,000 South Salem sewerage order.

New Castle, Pa.—The City Engr. has been directed to prepare plans for a lateral sewer system for the north end of the 7th Ward.

Seneca Falls, N. Y.—The Municipal Bd. has received maps of the village from Allen & Farrington, of Syracuse, who established grades for sewers, pavements and sidewalks. The maps show 14 miles of sewers necessary for the complete system, the construction of which it is estimated will cost $68,000.

Baltimore, Md.—Major Venable's sewer ordinance, which has been referred to the Com. on Sewerage, provides for the appointment of an engineer to prepare and report to the City Council a plan for a general sewerage system for the city, appropriating $25,000 for expenses.

Syracuse, N. Y.—The Common Council has received from City Engr. Schnauber an estimate of $17,500 for cost of the proposed improvement of Harbor Brook for drainage purposes.

Newark, N. J.—Bids are wanted Oct. 16 for building Section 6 Millburn-Summit division of the joint outlet sewer, as advertised in The Engineering Record.

Washington, Pa.—An ordinance has been passed providing for the construction of a sewer on Jefferson Ave. F. H. Judson, Ch. Burgess.

Reading, Pa.—The Council has passed an ordinance authorizing the Bd. of Pub. Wks. to construct a 20-in. storm water sewer on Walnut St. from 12th to 14th Sts.

Washington, D. C.—Bids will be received by the Comrs. D. C. until Oct. 18 for furnishing and erecting ready for use the pumping machinery, boilers and auxiliaries required to equip a sewage pumping plant at the Industrial Home School in the Dist. of Columbia. John Biddle, Comr. D. C.

Yonkers, N. Y.—Local press reports state that bids will be opened by the Common Council on Oct. 13 for a relief sewer in McLean Ave. and Van Cortlandt Park Ave. to Post St. Resolutions are under consideration for the construction of several other sewers.

Bayonne, N. J.—It is stated that bids are wanted Oct. 7 for constructing sewers in Ave. C, 16th, Evergreen and West 9th Sts. Everett Smith, City Engr.

Ardmore, Pa.—The Com. of the Lower Merion Township Comrs., to whom was referred by a vote of the people the matter of borrowing $350,000 for the construction of a sewer system and the purchase of property and erection of municipal buildings, has agreed to recommend to the Comn. that the proposed loan be reduced to $250,000, the municipal building proposition being abandoned temporarily.

Kingston, N. Y.—According to local press reports the contract is about to be let for the construction of a sanitary sewer through E. O'Reilly St., Jansen Ave. and Prince St.

Philadelphia, Pa.—Bids are wanted Oct. 7 for constructing main and branch sewers. Cost, according to local press reports, to be about $500,000, of which $425,000 will be expended for 7 main sewers. Wm. C. Haddock, Dir. Dept. of Pub. Wks., Bureau of Surveys.

Newark, N. J.—The following bids were opened Sept. 25 for building Section 4, Second and Third Divisions of the West Branch of Joint Outlet Sewer. Alexander Potter, New York City, Ch. Engr.

York, Pa.—The proposition to increase the city's indebtedness $400,000 for the construction of a sanitary sewerage system is now being considered by the taxpayers.

La Grange, Ga.—The contract for constructing 49,300 ft. of 6 to 18-in. pipe sewers, with 96 manholes and 18 flush tanks has been awarded to Moore & McCrary, Atlanta, Ga., for $21,196.

Alliance, O.—It is stated that bids are wanted Oct. 13 for $90,000 sanitary sewer bonds.

Girard, O.—It is stated that bids are wanted Oct. 20 for survey, plans and specifications for a sewer system in this village. E. L. Hauser, Corporation Clk.

Iola, Kan.—It is stated that bids are wanted Oct. 16 for constructing sewer outlet, septic basins, mains and laterals for Sewer Dist. No. 1. J. H. Harris, City Engr.

Cass Lake, Minn.—Bids will be received by W. S. Cobb, Village Recorder, until Oct. 15 for constructing a sewer system in this village.

Cincinnati, O.—Bids will be received by the Bd. of Pub. Service until Oct. 28 for improving a portion of Linwood Ave., by constructing a trunk sewer and drains. Geo. F. Holmes, Clk.
The Bd. of Public Service has adopted specifications for a trunk sewer in Rieder St., Liston Ave. and Portland St. Estimated cost, $30,713.

Springfield, Ill.—The Council has passed an ordinance providing for an 18-in. pipe sewer in Pasfield St.

Toledo, O.—Bids are wanted Oct. 20 for furnishing material and constructing 8 and 10-in. circular pipe sewers in portions of 2 streets. Chas. H. Nauts, City Clk.

Marion, Ind.—Bids are wanted Oct. 21 for constructing a sanitary sewer. C. G. Robbins, City Clk.

Kenton, O.—Bids are wanted Oct. 22 for $11,000 sewer bonds. John P. Dougan, City Clk.

Tomah, Wis.—Press reports state that surveys are being made for a sewer system.

Vincennes, Ind.—Bids will be received by the Common Council until Oct. 27 for constructing 5th and Church St. sewer, Broadway and St. Clair St. sewers. Thos. Robertson, City Clk.

St. Joseph, Mo.—Ordinances have been introduced in the Municipal Assembly for the construction of five sewers in Dist. 78.

Pontiac, Mich.—The City Engr. has been instructed to report on the cost of constructing a girder and cement bridge.

Pekin, Ill.—Local press reports state that the citizens of Mackinaw Township will vote upon the building of a $5,000 bridge across Mackinaw River.

Elizabethtown, O.—Local press reports state that the following bids were opened by the Co. Comrs., Sept. 24, for constructing the superstructure of the Elizabethtown bridge; Engineer's estimate, $115,000; Bellefontaine Bridge Co., Bellefontaine, $129,570; Massillon Bridge Co., Massillon, $114,900; King Bridge Co., Cleveland, $121,600; Champion Bridge Co., Wilmington, O., $140,162; Variety Iron Wks., Cleveland, $133,361; Huston & Cleveland (2 bids), $112,000 and $116,000; Brackett Bridge Co., Cincinnati (3 bids), $105,600, $108,500 and $114,000.

Marion, Ind.—It is stated that the Cleveland, Cincinnati, Chicago & St. Louis R. R. and the Toledo, St. Louis & Western R. R. Companies are having plans prepared for a $100,000 bridge which the said roads propose building between Marion and North Marion.

Danville, Ill.—City Engr. W. H. Martin writes that the construction of a bridge over the North Fork of Vermilion River is contemplated. Estimated cost, $10,000.

Cleveland, O.—Bids will be received by the Bd. of Co. Comrs. until Oct. 15 for constructing a culvert on the North Ridge Road in Dover Township and a culvert on Dille Road, Nottingham. Julius C. Dorn, Clk.

Marysville, Kan.—Bids will be received by the Bd. of Co. Comrs. until Oct. 9 for constructing several steel bridges, the largest to be 100 ft. long. John Montgomery, Co. Clk.

Spencer, Ind.—Bids are wanted Oct. 18 for constructing a bridge across White River, between Owen and Marion Counties. Address Co. Aud., Spencer.

Suamico, Wis.—Bids are wanted Oct. 8 for constructing a steel bridge with stone abutments across Big Suamico River, in this city. Address Co. Clk., Green Bay.

South Bend, Ind.—Local press reports state that the Elkhart, South Bend & Chicago Ry. Co. has made a proposition to the city to construct a $45,000 bridge across St. Joseph River at Colfax Ave., or, to contribute $45,000 toward a structure which the city may build at said avenue, provided a franchise to construct, maintain and operate a street railway in the city is granted to the said company.

Kalamazoo, Mich.—Bids for the construction of storm sewers were opened Sept. 23 as follows (all bids rejected):

Bidders.	Portland cement concrete. 42 inch.	36 inch.	33 inch.	30 inch.	Excavation. Under 6 ft.	6 to 8 ft.	8 to 10 ft.	10 to 12 ft.	Manholes.	Totals.
Geo. Rickman, Kalamazoo	$2.80	$2.65	$2.50	$2.25	$.70	$1.00	$1.20	$2.40	$55	$19,524

B. F. Roe, Kalamazoo	2.65	2.50	2.35	2.10	.78	1.05	1.35	2.58	53	18,943
Wheeler & Pitkin, Kalamazoo	2.83	2.70	2.51	2.29	.70	1.05	1.18	2.37	59	19,621

Birmingham, Ala.—The Bd. of Aldermen has confirmed the ordinance providing for storm sewers on Southside, beginning at 19th St. and Alley F; estimated cost, $45,000.

Nashville, Tenn.—See "Paving and Roadmaking."

Marysville, Cal.—At a recent citizens' meeting a resolution was passed requesting the City Council to employ an engineer to make a report with regard to the sanitary condition of the city and to report on the disposal of all sewage.

San Francisco, Cal.—The Bd. of Superv. has passed an ordinance directing the reconstruction and completion of the 6th St. sewer at a cost of $50,250.

BRIDGES.

Center Rutland, Vt.—At a town meeting held Sept. 22 the residents of Rutland refused to contribute 40% of the cost of constructing a street railway bridge across Otter Creek at Center Rutland. A correspondent writes that it is likely that the Rutland St. Ry. Co. will construct an independent steel bridge. Address David Fox, Jr., Gen. Mgr. of Ry. Co., Rutland, Vt.

Springfield, Mass.—The increase of the accommodations of the present bridge or the building of an entire new structure across the Boston & Maine tracks at Plainfield St., is being considered.

Elizabeth, N. J.—The building of a steel bridge across Elizabeth River at Prince St. is being considered.

New York, N. Y.—Comr. Eustis, of the Bronx Parks, has secured from the Bd. of Estimates an appropriation of $350,000 with which to construct a bridge in place of the Pelham Bay structure.

Downingtown, Pa.—The Co. Comrs. have granted the West Chester St. Ry. Co. permission to construct a bridge on Lancaster turnpike, in Downington. W. A. MacDonald, Secy. Ry. Co., West Chester, Pa.

Danville, Pa.—It is stated that the Delaware, Lackawanna & Western R. R. Co. is to build a single span, steel truss bridge across Mahoning Creek, in this city. W. K. McFarlin, Ch. Engr., Hoboken, N. J.

Millhall, Pa.—Engineers are reported to be surveying for a 3 span iron bridge, which is to be built across Fishing Creek.

St. Joseph, Mo.—Press reports state that an agreement has been reached between the Grand Island & Rock Island R. R. Cos., whereby a $400,000 bridge is to be built across Missouri River at St. Joseph. It is stated that bids will be asked in the near future.

Danville, Ill.—John Beard is reported to have secured the contract to construct a bridge across Vermillion River at Jenkins Ford, in Georgetown Township, for $12,895.

Kankakee, Ill.—The Ind., Ill. & Ia. R. R. Co. will build a plate girder bridge over the Kankakee at this place. Estimated cost, $40,000. Contract for the piers and abutments has been awarded to the McLaughlin Const. Co., of Kankakee, for about $15,000.

St. Charles, Mo.—Bids will be received until Oct. 16 by Carr Edwards, Co. Surv., for building several small steel bridges and for repairing several other small bridges.

Chattanooga, Tenn.—Press reports state that the officials of the Knoxville & Augusta R. R. intend constructing a steel viaduct across Tennessee River in this city, at a cost of $60,000. W. P. Hood, Gen. Supt., Knoxville, Tenn.

Portland, Ore.—The building of a steel bridge at Grand Ave. is being considered.

Los Angeles, Cal.—H. Hawgood, Ch. Engr. of the San Pedro, Los Angeles & Salt Lake R. R. is reported to have prepared plans for a solid concrete bridge that is to be built across Santa Ana River, in Los Angeles Co., Cal. It is reported that the bridge will be 800 ft. long and 24 ft. wide, consisting of 8 spans, 86 ft. in the clear, and piers 14 ft. thick and 64 ft. high.

Belfield, N. D.—See "Railroads."

Aberdeen, Wash.—Bids are wanted Oct. 25 for $20,000 bridge bonds. Geo. A. Black, Clk.

PAVING AND ROADMAKING.

Boston, Mass.—The estimated cost of macadamizing Cornell St., West Roxbury, is placed at $20,000.

New York, N. Y.—Bids are wanted Oct. 9 for resetting curb and edging and resurfacing walks and lawns and other work in Corlears Hook Park, also for resetting curbstones and paving with granite block pavement portions of the roadway of W. 96th St., between West End Ave. and the right of way of the Hudson River R. R. Wm. R. Willcox, Comr. of Parks.
Bids will be received until Oct. 7 by Jacob A. Cantor, Boro. Pres., for regulating, grading and paving with asphalt on portions of numerous streets, in all about 50,516 sq. yds. of pavement, including binder course, and 45,890 sq. yds. of old stone pavement to be relaid as foundation and in approaches; also for paving about 4,761 sq. yds. with asphalt block and 1,200 sq. yds. with granite block.

Jersey City, N. J.—Bids will be received by the Bd. of Street & Water Comrs. until Oct. 7 for improving portions of 3 streets, work to include 4,174 sq. yds. of Belgian paving and 2,790 sq. yds. of asphalt paving. Geo. T. Bouton, Clk.

Brooklyn, N. Y.—The lowest bid for grading 61st St. from 4th to 5th Aves. (bids opened Oct. 1) was that of Chas. J. Bofrie at 26 cts. per cu. yd. for 38,880 cu. yds. earth excavation.

Buffalo, N. Y.—The Bd. of Park Comrs. has adopted a resolution providing for the construction of a boulevard along the east bank of the Genessee River to Seneca Park, east. Estimated cost, $11,100.

No. 16 (bids opened Sept. 22) has been awarded to the Green River Asphalt Co., St. Louis, Mo., which bid was as follows: Class "A," rock asphalt, 5-in. native cement concrete, 2½-in. wearing surface, 4,000 sq. yds., 10-year guarantee, at $1.89 per sq. yd.; Class "A," vit. brick, for gutters, with 5-in. native cement concrete, 1½-in. sand cushion and 4-in. brick, 1 year guarantee, 3,550 sq. yds. at $1.75 per sq. yd.; Class "2," artificial stone curbing, 5,420 lin. ft., 5-in.x20-in., at 36 cts. per lin. ft.; broken stone, $2.05 per cu. yd.; cement filler, 11 cts. per sq. yd.

Denver, Colo.—The Bd. of Pub. Wks. is stated to have received the following bids for resurfacing, with disintegrated granite 2 to 2½ ins. thick, the roadway of Capitol Hill Improv. Dist. No. 1 (total area, 140,000 sq. yds.): The Colorado Paving Co., at 23¾ cts. per yd., $33,250; Thos. J. Tully, at 25 cts., $35,000, and Chas. Connors, at 27 cts., $37,800.

Omaha, Neb.—Bids are wanted Oct. 10 for improving a portion of 21st St., by paving with asphaltum, vitrified brick, stone block or vitrified block and for curbing with artificial stone or artificial stone combined curb and gutter. Wm. Coburn, Secy. Bd. Pub. Wks.

Winnipeg, Man.—The City Council has decided to improve a portion of George Ave. by paving with asphalt to a width of 24 ft., and curbing with cut stone. Estimated cost, $8,720. C. J. Brown, City Clk.

Montreal, Que.—Local press reports state that plans are now being prepared at the City Hall for the construction of the proposed boulevard for the Island of Montreal; plans call for a main boulevard 300 ft. wide for a distance of 30 miles; also side boulevards to run to the principal towns.

POWER PLANTS, GAS AND ELECTRICITY.

South Norwalk, Conn.—The Council Com. is reported to have recommended the construction of a city electric light plant.

Lewiston, N. Y.—Philip Pitz is reported to be Chmn. of a Com. appointed to investigate the cost of installing an electric plant.

Glen Gardner, N. J.—The Hunterdon Electric Light & Power Co. is reported organized here, to furnish power and light the town.

Castile, N. Y.—It is stated that bids are wanted by J. S. Chapman, until about Oct. 15, for constructing a power plant to cost about $10,500. There will be 30 arc and 650 incandescent lamps. Wm. J. White, Engr., 111 White Bldg., Buffalo, N. Y.

Staunton, Va.—E. M. Funkhouser, of Staunton, who recently purchased the Staunton Light & Power Co.'s plant, writes that improvements are contemplated in the electric lighting.

Marion, O.—Henry Strelitz and John A. Huber have petitioned the Council for a franchise for a heating plant.

Grand Rapids, O.—The Council is stated to have granted Augustine Pillod a franchise to light the town by electricity.

Arcadia, O.—The Council is stated to have granted P. A. Wheeland, a franchise to light the streets by electricity.

Marion, O.—It is reported that the electric plant at the Susquehanna Silk Mills will cost $18,000. The mills will be thoroughly wired and equipped with electricity. H. Klert is Gen. Supt. of the mills.

Decatur, Ill.—R. E. Pratt, of Chicago, and Harvey Bates, of Indianapolis, Ind., are reported interested in the construction of an electric light plant at Decatur.

Ann Arbor, Mich.—A press report states that a survey of the Huron River is in progress for a new dam west of the city on the site of the old McMahon dam, where it is said the Washtenaw Power Co. proposes to put in a plant for the purpose of furnishing power and light to Jackson, Grass Lake, Chelsea and Dexter.

Sweet Springs, Mo.—See "Water."

Hubbardston, Mich.—The Village Council is reported to have voted to contract for an electric light plant.

Wyandotte, Mich.—The Ecorse Township Bd. is stated to have granted the Wyandotte Gas Light & Fuel Co. a franchise to sell gas in the Township.

Trenton, Mich.—Pres. Stokes is stated to have received an estimate of the cost of a municipal lighting plant from Village Engr. Keating, who states that a 125-H.-P. engine with a 60-Kw. electrical machine capable of supplying 25 street lights and 1,000 incandescent lights should not cost more than $5,315. This does not include additions to the water works, pump house or a boiler to develop steam to run the electrical machinery. It is stated that the citizens will be asked to bond for $10,000.

Lansing, Mich.—The State Bd. of Agriculture is reported to have approved the plans of E. A. Bowd, of Lansing, for a building for heating and lighting plant. The specifications call for a brick building 1 story high. The plant will cost about $125,000.

Winona, Minn.—Plans and specifications are being prepared and it is expected to ask for bids about Dec. 1 for a municipal electric light plant. Two plans are under consideration, one for 250 lights of 2,000 c. p., and one for 350 lights of 1,600 c. p. G. P. Coleman, City Engr.

Colby, Wis.—"See "Water."

Iowa City, Ia.—Thos. C. Carson, Pres. of the Iowa City Gas Light Co., writes that it is proposed to enlarge and remodel said company's plant at a cost of about $30,000, but work will not be done until 1903.

Akron, O.—The Co. Comrs. are stated to have granted the East Ohio Gas Co. a 25-year franchise to construct and maintain a line of gas mains and a telegraph line through Summit Co.

Cleveland, O.—The Northern Ohio Natural Gas & Pipe Line Co., of Cleveland, is reported to have been incorporated at Columbus Sept. 30 to pipe natural gas from the central part of the State to cities and towns in Northern Ohio. The intention of the new company is said to be to supply natural gas to such cities as Elyria, Lorain, Norwalk and Sandusky.

Chattanooga, Tenn.—The date for receiving bids for lighting the streets and public buildings has been changed from Oct. 7 to Oct. 28, as advertised in The Engineering Record.

Huntsville, Ala.—The City Council is stated to have decided to construct a municipal electric light plant.

Del Rio, Tex.—The Del Rio Electric Light & Power Co. has been incorporated, with a capital of $8,000. Incorporators: Fred Mayer, Henry C. Mayer and John M. Gray.

Crockett, Tex.—J. B. Smith is reported to have organized a company to build new electric light works and ice factory. This plant will supply the place of the one recently destroyed by fire.

Little Rock, Ark.—The City Council is stated to have granted W. H. Hipolite a franchise for a gas plant.

Lubbock, Tex.—The Lubbock Electric Co., of Lubbock, has been incorporated; capital, $2,500. Incorporators, C. E. Spath, M. C. Abernathy and H. S. Graham.

Flandreau, S. D.—City Aud. E. G. Coleman writes that on Sept. 25 it was voted to issue $8,000 bonds for the construction of a gasoline gas plant.

Columbus, Neb.—See "Water."

Thermopolis, Wyo.—The Thermopolis Electric Light & Power Co. has been incorporated, with a capital of $10,000, to build a light plant at Thermopolis. Chas. Wallace and John L. McCoy are among the incorporators.

Stanton, Neb.—The dam of the Stanton Water Power Co. recently completed at a cost of $7,500 is reported to have been carried away.

ELECTRIC RAILWAYS.

Biddeford, Me.—W. B. Getchell, of Augusta, Me., is making surveys for 12 miles of electric railway from Biddeford City to Biddeford Pool and Fortunes Rocks E. A. Hubbard, Dir.

Tiverton, R. I.—A petition is reported to be in circulation in Tiverton, asking that the Old Colony St. Ry. Co. extend its line to Bliss Four Corners and to Adamsville. Colon M. Ingersoll, Jr., Ch. Engr., New Haven, Conn.

Foxboro, Mass.—The Norton & Taunton St. Ry. Co. is stated to have petitioned the State R. R. Comrs. for permission to extend its line into Foxboro and Sharon. C. E. Short, Ch. Engr., Norton.

Duncansville, Pa.—The Boro. Council is stated to have granted a franchise to the Altoona Belt Line St. Ry. Co.

Brooklyn, N. Y.—Plans have been prepared by the Brooklyn Rapid Transit Co. for placing an arch over its tracks between 38th and 39th Sts., from 4th to 8th Aves., So. Brooklyn, and filling in the cut there, which is 30 or 40 ft. deep. J. C. Brackenridge, Chief Engr., 168 Montague St.

Red Bank, N. J.—Alfred Stoney, of Keyport, and Wm. Taber Parker, of Little Silver, are reported interested in the construction of an electric railway between Red Bank and Oceanic.

Doylestown, Pa.—The Town Council is stated to have granted a franchise to the Doylestown & New Hope Ry. Co.

Loysville, Pa.—The Loysville Trolley Co. is stated to have secured the entire right of way for its line, and the work of surveying will begin at once.

Pittsburg, Pa.—The Pittsburg Railways Co. is reported to have secured control of the franchises of the Pittsburg, Coraopolis & Monaca St. Ry., and will soon begin constructing the line; the company also proposes doubling its tracks from the head of Neville Island to Coraopolis. F. Uhlenhaut, Ch. Engr., Pittsburg.

Laurel, Md.—A press report states that Geo. H. Harries, Vice-Pres. of the Washington Ry. & Electric Co., and W. H. Fuller, Gen. Mgr. of the same system, both of Washington, D. C., were here on Sept. 25 and went over the route of the proposed railway from Laurel to Brookeville, via Sandy Spring.

Frederick, Md.—A charter has been granted to the Frederick & Jefferson Electric Ry. Co., with a capital of $125,000, to construct an electric railway from Frederick to Jefferson, a distance of about 8 miles. Lewis O. Whipp and C. E. Lakin are among the incorporators.

New York, N. Y.—Plans have been filed for two 3-story brick sub stations for the underground Rapid Transit Railroad, to be built, one at 29 to 33 City Hall Place, 58x99 ft., to cost $60,000; the other at 108 to 110 E. 19th St., 50x91 ft., to cost $55,000. They will be of granite and limestone with terra cotta trimmings. Plans have also been filed for a 1-story inspection shed, to be built at 148th St. and 7th Ave., being 338 ft. front by 199 ft. deep. This building is to be constructed of re-enforced cement work supported by a structural steel framework, and will be used for the inspection of cars, etc., and will cost $95,000. The Rapid Transit Subway Constr. Co. is the owner. Van Vleck & Hunter, Park Row Bldg., are the architects.

Kirkland, N. Y.—The Oneida Ry. Co. is stated to have secured a right of way through the village. G. Leggett, Supt., Oneida.

Hazleton, Pa.—A charter has been granted to the Hazleton, Weatherly & Mauch Chunk Traction Co., with a capital of $100,000, to construct an electric railway about 15 miles in length. Incorporators: Frank W. Larned, Wilkesbarre; Lawrence Tarleton, of Weatherly, and others.

Morgantown, W. Va.—A press report states that the Morgantown Electric Light & Power Co. has sold $300,000 bonds, a large portion of which will be spent in building ten miles of trolley line.

Dunbridge, O.—The Toledo, Bowling Green & Southern Traction Co. is reported to have secured a right of way from Dunbridge to Toledo. W. Nusbaum, Ch. Engr., Cincinnati.

Greenville, O.—The Greenville & Union City Traction Co., of Greenville, is reported incorporated with a capital of $75,000, by Jos. E. Lowes, T. J. Weakley, and others, to construct an electric line from Greenville to Union City.

Middletown, Ind.—The Town Bd. is stated to have granted a franchise to the Union Traction Co., of Indiana. G. F. McCulloch, Gen. Mgr., Anderson.

Jasper, Ind.—A corps of engineers, under Robt. W. Hunt & Co., of Chicago, Ill., are reported to have commenced surveying for an electric line from this place to Mitchell, Ind., by way of French Lick and West Baden.

Frankfort, Ind.—Wm. George, of Aurora, Ill.; O. V. Darby, of Kokomo, Ind., and D. A. Coulter, of Frankfort, are reported interested in the construction of an electric railway from Frankfort to Logansport, and from Kokomo to Lafayette.

Muncie, Ind.—A correspondent writes that the survey for the Muncie-Portland Interurban Ry. has been completed, and that the line will probably be completed in the early part of 1903.

Paxton, Ill.—The Paxton, Danville & Wilmington Ry. Co. has been incorporated to construct a line from Danville through Paxton, Potomac and other towns to Wilmington; capital, $5,000. Directors: J. K. Butz, Potomac; W. O. Johnson, Paxton, and J. W. Dale, Danville, and others.

Madison, Wis.—The Madison & Northeastern R. R. Co. is reported incorporated to build an electric railway from Madison to Oshkosh and Fond du Lac via Sun Prairie, Columbus, Beaver Dam and Waupun. The line will be 130 miles in length. Incorporators: Chas. Scherleker, Sun Prairie; Frank Stegerwald, East Bristol; R. Bailey, Waupaca, and others.

Marquette, Mich.—Wm. K. Rhoades, of Cleveland, O., is promoting the building of an electric railway from Marquette to Negaunee and Ishpeming, a distance of about 14 miles. It is proposed to build the road so that the heavy snowfalls will not interfere with traffic. Power will be generated at the Dead River Falls, 4 miles from Negaunee.

St. Louis, Mo.—The St. Louis Co. Court at Clayton, Sept. 25, granted a franchise for a street railway over the Olive St. road to Creve Coeur Lake to the St. Louis County St. Ry. Co., of which Judge H. W. Bond is Pres.

Cincinnati, O.—The Cincinnati, Milford & Loveland Traction Co., of Cincinnati, has been incorporated, with a capital of $700,000. Incorporators: B. H. Kroger, J. Nevin Roberts and others.

Ft. Wayne, Ind.—P. A. Randall, of Ft. Wayne, is reported interested in the construction of an electric railway between Ft. Wayne and Garrett; also to Waterloo and Avilla.

Louisville, Ky.—Local press reports state that articles of incorporation have been filed by a company which proposes to turn the present Louisville, Harrods Creek & Westport R. R. into an electric line. The property has been leased from the Louisville & Nashville R. R., and the new company has an option and may become absolute owners later on. The new company has a capital of $350,000. Directors: Bethel Veach, W. N. Cox, Lafon Allen and others.

Falls City, Neb.—The Sycamore Ry. & Improvement Co. has been incorporated, to construct an electric road from Falls City south to Topeka, Kan., and north to Auburn, Neb. Incorporators: E. V. Kauffman, John H. Judy, Roy Hesseltine, and others.

Seattle, Wash.—T. O. Abbott, a local attorney, representing F. M. Wade, of Portland, Ore., is stated to have petitioned the Council for a franchise for a railway to cover about 20 miles of streets.

Santa Barbara, Cal.—It is stated that bids are wanted Oct. 13 for a franchise to construct an electric street railway on certain streets in this city. Alfred Davis, City Clk.

RAILROADS.

Wellsburg, W. Va.—A press report states that a charter has been granted to the Wellsburg & State Line R. R. Co. to construct a railroad up Buffalo Creek.

Duluth, Minn.—The Duluth, Virginia & Rainy River R. R. Co. is reported to be considering the extension of its line to Pelican Lake.

Nashville, Ill.—Lewis Krughoff, Julius Huegely and others, of Nashville, are reported interested in the construction of a railroad from Springfield to Murphysboro through Nashville, Pinckneyville, Greenville, Carlyle and Hillsboro.

Maryville, Tenn.—A charter has been granted to the Tennessee & Carolina Southern Ry. Co., with a capital of $200,000, to construct and operate a railway from a point of connection with the Southern Ry. at Maryville, through the counties of Blount and Monroe to a connection with the railway of the Carolina & Tennessee Southern, a distance of about 40 miles. Incorporators: Leon Jourolmon, Henry Fonde and others.

Memphis, Tenn.—A press report states that work will soon be commenced by the Arkansas, Missouri & Kansas Ry. Co., which proposes constructing a line from Memphis, through Joplin, Mo., to Chanute, Kan.

Birmingham, Ala.—Maj. J. W. Bushnell, Eng. in charge of the construction work of the Seaboard Air Line R. R., is reported to be in Birmingham arranging to let contracts for construction work on the line between Coal City, on the East & West R. R., to Birmingham, a distance of about 37 miles. The East & West is owned by the Seaboard and is to be rebuilt entirely from Cartersville, Ga., to Pell City. W. W. Gwathmey, Jr., Ch. Engr., Portsmouth, Va.

Geneva, Ala.—W. W. Barnett, J. J. Morris and J. R. Clarke, all of Geneva, are reported to have applied to the Sec. of State for a charter for the Geneva R. R. Co. The road is to run from Geneva to a junction with the Chattahoochie and Gulf R. R.; capital is placed at $100,000.

Asher, Okla. Ter.—A press report states that the Rock Island R. R. will construct a line from Asher to Dallas, Tex. W. E. Dauchy, Ch. Engr., Chicago, Ill.

Harrodsburg, Ky.—A surveying corps of the Southern Ry. (C. M. Ackert, Gen. Mgr., Washington, D. C.) is reported to be surveying for the extension of the Louisville Southern from Harrodsburg to Danville.

Babcock, Wis.—Bids will be received by J. E. Ingraham, Secy. Remington Drainage Dist., Babcock, for dredging about 350,000 cu. yds.

New Orleans, La.—Local press reports state that the Dock Comrs. are about to let contracts for the construction of 4 new steel sheds. Coleman, Malochee & Villere, Engrs. of the Bd. are now preparing plans for these sheds, which are to be located at Clouet St. wharf, Picayune tier, Orange St. and the new Market St. wharf.

NEW INDUSTRIAL PLANTS.

The Reliance Mfg. Co., Winchester, Ky., will erect a wood-working plant to replace that recently burned. The main building will be 100x250-ft., and the power plant, 150 H.-P.

H. Abrams, Winston, N. C., contemplates erecting a new factory.

The Griffin, Ga., Mfg. Co. will build additions to its plant during the coming year, but no definite plans have been made.

The Hewson Woolen Mills, Amherst, N. S., will install a power plant of 150 to 200 H.-P., the boilers to be two of 125 H.-P. each.

The Oneida Knitting Co., De Pere, Wis., will erect a 2½-story, 120x50-ft. mill, to be driven electrically and heated by steam.

Plans have been prepared for a 3-story brick mill to cost about $20,000 for the Eaton-Hurlbut Paper Co., Pittsfield, Mass.

Tillman Bros., Reepsville, N. C., will erect a 4-story, 30x40-ft. flour mill and a 22x30-ft. engine house at North Brook, N. C. They are in the market for a 30-H.-P. engine and a 35-H.-P. boiler.

The Bridal Veil, Ore., Lumbering Co. is having plans drawn for a new mill.

E. W. Wilbur, Mesa City, Ariz., expects to be in the market within 60 days for equipment for a creamery, including refrigerating plant and a 10-ton ice machine.

The Hamilton, O., Brick Co. will build a plant having a daily output of 40,000 or 50,000 in the early spring. An engine of about 50 H.-P. and the necessary boilers will be installed.

The New York Air Brake Co., 66 Broadway, New York, is erecting a 272x300-ft. foundry at Watertown, N. Y., to have a daily capacity of 100 tons. Steam power will be used during the winter, but by next summer it is hoped to install electricity.

The Huntington, W. Va., Cold Storage & Commission Co. is erecting a cold-storage house having a capacity of 250,000 cu. ft., an ice plant having a daily capacity of 35 tons, and a 1,000-ton ice-storage house.

Milam & Williams, Watauga Valley, Tenn., will erect a 28x40-ft. flour mill next spring, to have a capacity of 30 to 40 bbls. The capacity of the power plant will be 42 H.-P.

The American Cabinet Co., Canisteo, N. Y., which has absorbed the Smith Table Works, Warren, Pa., has broken ground at Fairmount, near Buffalo, N. Y., for a 100x200-ft. main factory building, 50x150-ft. finishing and packing room, 58x100-ft. dry-kiln and gluing house, and 40x60-ft. boiler, engine and pumping house. The cost of the plant will be $250,000. Geo. S. Davis, Warren, Pa., Supt.; L. M. Hewit, Canisteo, Chmn. Bd. of Directors.

The United Shoe Machinery Co., Albany Bldg., Boston, Mass., will erect a new plant at Beverly, Mass., to include a 3-story, 60x80-ft. administration building; two 3-story and basement, 600x60-ft. manufacturing buildings; a 3-story and basement, 300 to 400x60-ft. storage building; a 60x220-ft. drop forge, blacksmith, die sinking and hardening plant; a 20-ton foundry requiring 72,000 ft. floor space, and a 1,500 to 1,800-H.-P. central power plant. The plant will probably be driven electrically. F. M. Andrews, Dayton, O., architect; Dean & Main, Boston, consulting mechanical engineers.

BUSINESS NOTES.

The Chapman Fuel Economizing System of Albany has been incorporated with a capital of $35,000 to manufacture an invention of John S. Chapman for economizing fuel, arresting smoke and increasing steam boiler capacity. The directors are: John S. Chapman, Isaac La Grange, James W. Bentley and B. A. Chapman, of Albany; John Pressley, M. Pressley and M. Weighill, of Rochester.

The Ball Engine Co., Erie, Pa., reports the following among its recent orders: Detroit Iron & Steel Co., three 350-H.-P. engines, each arranged for direct connection to a generator; C. O. Lamson, Waterloo, Ia., an engine for direct connection to a Westinghouse generator; Penna. R. R. Co., Ft. Wayne, Ind., an engine for electric service; Pueblo, Colo., Electric Co., an additional unit.

The Otis Elevator Co. has recently closed a contract with the Rapid Transit Subway Const. Co., New York, for an escalator, or moving stairway, to be installed at the Manhattan St. station of the new rapid transit road. At this point the subway crosses the Manhattan Valley on a viaduct, the tracks being about forty feet above the level of the street. The escalator will carry passengers both up and down, the two tracks being arranged in the same vertical plane. The guaranteed carrying capacity of the device is 20,000 people per hr., 10,000 in each direction. A motor of 35 H.-P. will be sufficient to operate the mechanism when working at its maximum capacity.

The Buffalo & Susquehanna Iron Co., Buffalo, N. Y., has contracted with Wm. B. Scaife & Sons Co., Pittsburg, for a 6,000-H.-P. We-Fu-Go water softening and purifying system. This is the third plant purchased by that company, located at different points. Wm. B. Scaife & Sons Co. has now in successful operation over 200,000 H.-P., in the United States alone, handling over 25,000,000 gallons of water daily, principally for boiler use, although a part of this amount is used in industries where soft water is desirable.

The Crocker-Wheeler Co. held at its works at Ampere, N. J., on Sept. 25 and 26, its annual managers' convention. Those present were the officers of the company, Schuyler S. Wheeler, Gano S. Dunn, W. L. Brownell, Putnam A. Bates, C. N. Wheeler and F. V. Henshaw, and the branch managers, Samuel Russell, Jr., Julian Roe, J. Bally Craig, Louis P. Hall, W. H. Wissing, Francis B. DeGress, Henry J. Sage, William A. Doble and Harold Lomas. Francis B. DeGress, of the company's New York office, who has been in the service of the company longer than any of the other branch office managers, presented to the general sales manager, Putnam A. Bates, in the name of the managers, a token of their esteem.

The Chicago Pneumatic Tool Co. has declared a quarterly dividend of 2 per cent., payable Oct. 15; the capital stock of the company is $10,000,000. Appropriation was made to enlarge the Detroit plant, the addition projected to increase the company's capacity one-third. An order has been granted by the courts restraining the making, selling or use of tools in infringement of the Moffet patent owned by the company until the further order of the court.

Some of the contracts recently awarded the New England Structural Co. are the extension to the Boston & Maine shops at Concord, N. H., and bridges at Everett and Revere, Mass., for the same railroad, which are part of the system of elimination of grade crossings, which has been begun by the railroad.

The Engineering Record, conducted by Henry C. Meyer, is published every Saturday at 21 Park Row, New York. Its opinions on technical subjects are either prepared or revised by specialists.

Subscriptions are received and single copies supplied by the International News Company, Breams Building, Chancery Lane, London.

The subscription rate is $5 a year for the United States, Canada and Mexico, and $6 for other countries in the Postal Union. Remittances should be made by check, New York draft or money order in favor of The Engineering Record. No responsibility is assumed for payments made otherwise, except those for subscriptions to the International News Company.

The Durability of Concrete-Steel Construction.

One of the most important elements or characteristics of any class of engineering construction is its durability. This quality is generally taken to mean the capacity of the material to resist physical deterioration through chemical changes, such as oxidation in the case of iron and steel, or of decay in the case of timber. The same general deterioration, i. e., that arising from chemical changes, plays an important part in the length of life of many of the less valuable building stones. Deterioration due to chemical changes, therefore, has come to be considered even among civil engineers as the crucial test of the durability of perhaps every class of engineering construction. While in one sense the test of capacity to resist this kind of deterioration may be a proper general criterion, it is not by any means all that must be carefully regarded. There are other features of structural materials and combinations of materials which have frequently a controlling influence on durability, although chemical action may finally play a substantial part in the ultimate results. There is no single class of structural work on which these observations bear more forcibly than on the concrete-steel combination.

Concrete-steel construction possesses characteristics which give it perhaps the possibility of the widest and most varied application of all materials yet employed by the engineer. As a class of masonry it may be advantageously used wherever the conditions are such as to require the use of any grade of masonry, including all varieties of foundation or subaqueous work, retaining walls or other walls of structures, all parts of floors and even much of the ornamental parts of buildings. Among its varied duties is included the resistance to tension, where the tendency is to form cracks and so give play to the various deteriorating influences known as weathering. In other words it may be subject to practically every kind of exposure which any engineering structure whatever may be required to meet. It has already found its way into such extended applications, and is so seriously considered for others, that there have been active discussions among engineers as to the degree of durability which future experience with it may be expected to disclose.

At the annual convention of the American Society of Civil Engineers in May last, one of the subjects brought before it was in essence if not in name the durability of the composite of concrete and steel, and the discussion in full may be found in the "Proceedings" for August. As might be expected there were some clear differences of opinion as to a number of details, although in the main the consensus of judgment favored the durability of steel embedded in concrete. The whole criticism, however, may be considered as being based upon the possible effects due to chemical changes, especially those produced by the penetration of dampness through the surrounding concrete to the steel enclosed in its mass. Although there are other most essential elements in the case, those of a more directly chemical nature may receive the first attention.

It is very generally admitted, if not invariably held, that if iron or steel be effectually covered with Portland cement, mortar or concrete, it will be completely protected from corrosion for an indefinite period. This view is abundantly supported by experience and there is practically no probability of future disclosures to the contrary. In spite of this, however, there is a feeling among at least a considerable number of engineers and architects that, under the usual conditions of construction, water in subaqueous work or storm water in exposed work above ground may percolate through the mass, and possibly produce oxidation of the embedded metal. Indeed, there are probably few engineers who would venture to use much steel below water level even when embedded in concrete if the strength of the work depended upon its preservation. This apprehension is probably well grounded in at least much of the concrete work of the past, but it does not follow from that that further improvements in putting concrete in place may not insure even the indefinite preservation of steel embedded in concrete under water. The defect of past concrete work as a preserving environment of iron and steel is chiefly due to the voids remaining in it in spite of such ramming or other compacting as may have been employed. It is almost, if not quite impossible to force all the voids out of dry concrete mixtures, but a much more nearly continuous mass may be reached by a wetter mixture. That is one of the advantages resulting from a comparatively wet concrete and there are probably others. Again there is considerable experience which goes to show that a mortar made with a suitable percentage of finely ground cement is practically impervious to water, at least sufficiently so for the requisite preservative effects on embedded iron and steel; indeed, some existing records of tests show that the same observation may be applied to concrete suitably made and put in place, even when the cement is of ordinary fineness only. It is believed that it is practicable under reasonable conditions of engineering construction to protect iron and steel for even subaqueous work, by either surrounding the metal immediately with essentially impervious mortar and concrete beyond that, or by suitably made concrete. In the latter event properly balanced proportions of sand and broken stone or gravel is a most important element in the quality of preservative impermeability. Results already obtained in actual work show that the attainment of these results is undoubtedly within the reach of practicable engineering operations, but that the fineness of cement grinding and the balancing of concrete elements materially influence the results. In the preceding observations it has been pointed out, essentially, that the actual continuity of the enclosing mass is imperative for complete protection. This is a feature which almost invariably escapes attention in the discussion of this subject. Yet it is clear that if cracks occur in the concrete, however continuous the mass may originally have been, avenues of entrance for water and all kinds of weathering are created. Fortunately most careful investigations have shown that the action of the steel, among other things, effectively prevents the occurrence of cracks that would otherwise certainly appear. It is one of the unexpected but most advantageous influences of the metal portion of the combination. M. Considère and others have demonstrated that the concrete surrounding a steel bar will stretch far beyond any limits possible when acting by itself; it may even stretch one five-hundredth of its length before parting. Again, experimental determinations during the past two or three years have conclusively shown that the thermal expansion and contraction of concrete (as well as other masonry) is so nearly identical with that of iron and steel that they may be considered the same. The two parts of the combination, therefore, move as a unit under temperature changes and there can be set up no internal stresses tending to separate them or to rupture either. These two latter qualities of the concrete-steel composite are effective influences in the maintenance of continuity of the concrete and, hence, in securing its impermeability. The effect of the embedded steel upon the durability is most important and of a value not yet fully recognized.

Technical Education was the subject of Prof. John Perry's recent presidential address before the engineering section of the British Association, and in the course of his remarks he paid his respects as follows to certain critics among practicing engineers: "When a man has become a great engineer, and he is asked how it happened, what his education has been, how young engineers ought to be trained, as a rule it is a question that he is least able to answer, and yet it is a question that he is most ready to answer. He sees that he benefited greatly by overcoming certain difficulties in his life; and forgetting that every boy will have difficulties enough of his own, forgetting that, although a few difficulties may be good for discipline, many difficulties may be overwhelming, forgetting also that he himself is a very exceptional man, he insists upon it that those difficulties which were personal to himself ought to be thrown in the path of every boy. It often happens that he is a man who is accustomed to think that early education can only be given through ancient classics. Being an exceptional boy, he did not altogether lose his natural inclination to know something of his own language; and he is in the habit of thinking that he learnt English through Latin, and that ancient classics are the best mediums through which an English boy can study anything. He forgets the weary hours he spent getting off Euclid, and the relief it was to escape from the class-room not quite stupefied; and he advocates the study of pure mathematics and abstract dynamics as absolutely necessary for the training of the mind of every young engineer. I have known the ordinary abominable system of mathematical study to be advocated by engineers who, because they had passed through it themselves, had really got to loathe all kinds of mathematics higher than that of the grocer or housekeeper. They said that mathematics had trained their minds, but they did not need it in their profession. There is no profession which so much requires a man to have the mathematical tool always ready for use on all sorts of problems, the mathematical habit of thought the one most exercised by him; and yet these men insist upon it that they can get all their calculations done for them by mathematicians paid so much a week."

A Four-Truss Double-Deck Railroad Bridge.—I.

Bridge No. 1 of the eastern division of the Pittsburg, Fort Wayne and Chicago Railway crosses the Allegheny River between Pittsburg and Allegheny. It has five pin-connected through channel spans on masonry piers about 35 feet high above mean water level, and is about 975 feet long on center line between abutments of end spans. The faces of the north abutment and the sides of the four intermediate piers are parallel and make an angle of 81° 51′ with the axis of the bridge. The south pier of the old bridge was remodeled and extended to serve as south abutment for the new structure and is at an angle of 91° 13′ with axis of bridge. Two of the piers are 10 feet wide and about 58 feet long under the coping and the other two are 12 feet wide and about 66 feet long to provide seats for the heavier trusses of the long span.

Each span has four trusses, three of which are in the same straight lines from end to end of the bridge, and the fourth are in line for the four western spans, but divergent for the eastern span. Each of the trusses in each of the four western spans has the same length as the other three trusses of the same span but in the eastern span the lengths of the trusses from center to center of end pins vary from 164 feet 2 5/16 inches to 157 feet 10 7/16 inch. There are three spans of 156 feet ½ inch and one span of 333 feet 3⅝ inches. In these spans the centers of the trusses are 9 feet and 26 feet 8 inches from the axis of the bridge. The base of the lower rail is 6 feet 6⅞ inches, and the center of lower chord pins is 7 feet 2⅞ inches above the top of the pier masonry in the 333 feet span and 4 feet 2½ inches and 4 feet 11⅝ inches, respectively in the other spans. The bridge is cambered as a whole so as to give a continuous parabolic curve with a horizontal chord 983.96 feet long and a 12-inch center vertical ordinate to the base of rail. This is effected by varying the heights of the pier tops and making the inclined lines which connect the centers of the spans the chords of a parabolic curve. For the camber of each span the center ordinates vary from 0.16 to 0.337 feet and the ordinates between them and the rail base are made in the framing of the cross ties.

The floor is of soft steel and is designed to conform to the standard floor for the Pennsylvania Lines West of Pittsburg. The field rivets are of wrought iron, the shop rivets are of mild steel, and all the remainder of the superstructure is of medium steel designed according to the standard specifications of the railway for 1897, with the stresses increased 20 per cent. for medium steel members. In the 333-foot span the loading assumed is, for the outside trusses, 2,980 pounds dead and 3,750 pounds live per lineal foot and 37,500 pounds concentrated. For the inside trusses, 6,380 pounds dead and 7,500 pounds live per lineal foot and 75,000 pounds concentrated. Wind pressure is assumed at 50 pounds per square foot for the unloaded and 30 pounds per square foot for the loaded structure, and at 600 pounds per foot for moving load. For the floor system the load per track is assumed at 5,000 pounds per lineal foot and at 50,000 pounds concentrated and the dead load of the track at 300 pounds per lineal foot.

It was required that the bridge should carry two pairs of tracks at different fixed levels and the vertical clearance between them was too small to allow for floor beams deep enough to carry two tracks; therefore the bridge was designed with four trusses so as to secure single track floorbeams. The two vacant panels in the transverse sections have been arranged above and below and on opposite sides and are at present occupied by sway bracing, one of them being utilized for a sidewalk between the diagonals, and the other one being designed to receive a third track at the upper grade if necessary in the future. The upper deck is made according to the usual standard of the North West system with four lines of stringers to each track. In the lower floor two more lines of stringers are added for each track and the whole lower deck is covered with plank and protected by railings to permit the ready handling of trains by the yard crews.

In the 333-foot span the lower chord panels are 23 feet 9 11/16 inches long, except in the end panels, which vary on account of the skewed ends. The vertical end posts are 27½ feet high, and the center three vertical posts are 63½ feet high. The bottom chord is horizontal, and the top chord is horizontal in the center two panels and inclined elsewhere. In the center trusses the maximum top chord stress is 3,235,000 pounds and the corresponding cross sectional area is 292.5 square inches. Maximum bottom chord stress 3,064,000 pounds, section 237.5 square inches. End vertical post, 2,224,000 pounds, section 202.5 square inches. End diagonal tie, 2,427,000 pounds, section 190 square inches.

As seen by the cross section diagram each center truss carries half the load from three tracks, while each outside truss carries half the load from one track, therefore the stresses in the side trusses are much lighter than those just given. The maximum top and bottom chord stresses and sections are 1,563,000 pounds and 146 square inches and 1,469,000 pounds and 116.25 square inches respectively, and the stresses in the other members are in proportion.

The trusses are braced together by the two floor systems, one of which is just below the lower chord pin level and the other is about 17 feet in the clear above it, and by transverse girders between the tops of all vertical posts and by lateral diagonals in the planes of the top and bottom chords. There are besides solid web knee braces at both ends of all floorbeams and on both top and bottom flanges of the beams in the upper deck. On one side of the bridge the upper and on the other side of the bridge the lower outside panel of every bent between vertical posts is stiffened transversely by riveted X-braces, thus providing great resistance to lateral deformation.

The bottom laterals are flat plates ½ inch thick and from 6 to 14 inches wide. Each one is stiffened by a 5x3½x⅜-inch angle riveted to the upper side, between stringer intersections. The top laterals are single clevis ended bars from 1⅜ inches to 2 7/16 inches square. All lateral diagonals extend across three panels longitudinally and are connected to each of the four trusses, thus completely X-bracing each panel between trusses and floorbeams. The intermediate center floorbeams are proportioned for a maximum moment of 7,530,000 pounds and have a 31¾x11/16-inch web, two 6x6x½-inch angles and three 16x½-inch plates, one full length, one 13 feet and one 10 feet long, in each flange. The outside and end floorbeams have somewhat lighter stresses and have the same depth of web and size of flange angles and plates, but are made with lighter metal.

The 26 feet 10¼-inch stringers have a maximum moment of 2,593,000 pounds and are made with a 26¾x⅜-inch web plate and two 6x6x11/16-inch flange angles. The flange stress is 110,200 pounds and its area 14.4 square inches. The lower outside panel not occupied by a railroad track has a sidewalk with floorbeams 32½ inches deep, having 4x3½x⅜-inch flange angles. The two stringers outside the four track stringers in each of the two lower deck tracks are made with a 26¾-inch x ⅜-inch web and two 5x3½x⅜-inch flange angles. In all work it was required that all rivets were ⅞-inch in diameter, and that their holes were punched ¾-inch and reamed except where the material was ⅞-inch or more thick where they were drilled from the solid. All holes in flats were also drilled from the solid and all holes for field connections were reamed to cast iron templates.

The skew is taken up in the varying lengths of the end panels, so that the intermediate transverse members are all at right angles to the trusses and their connections to the vertical posts are central. The end floorbeams are skewed to correspond with the angle of the pier axis and the end panel stringers have varying lengths and oblique connection angles. The pedestals, shoes and bed plates are square with the trusses and skewed with the pier masonry so that the line connecting their center points forms an offset line as indicated by the end floor beam webs in the drawing of half the end elevation of the bridge.

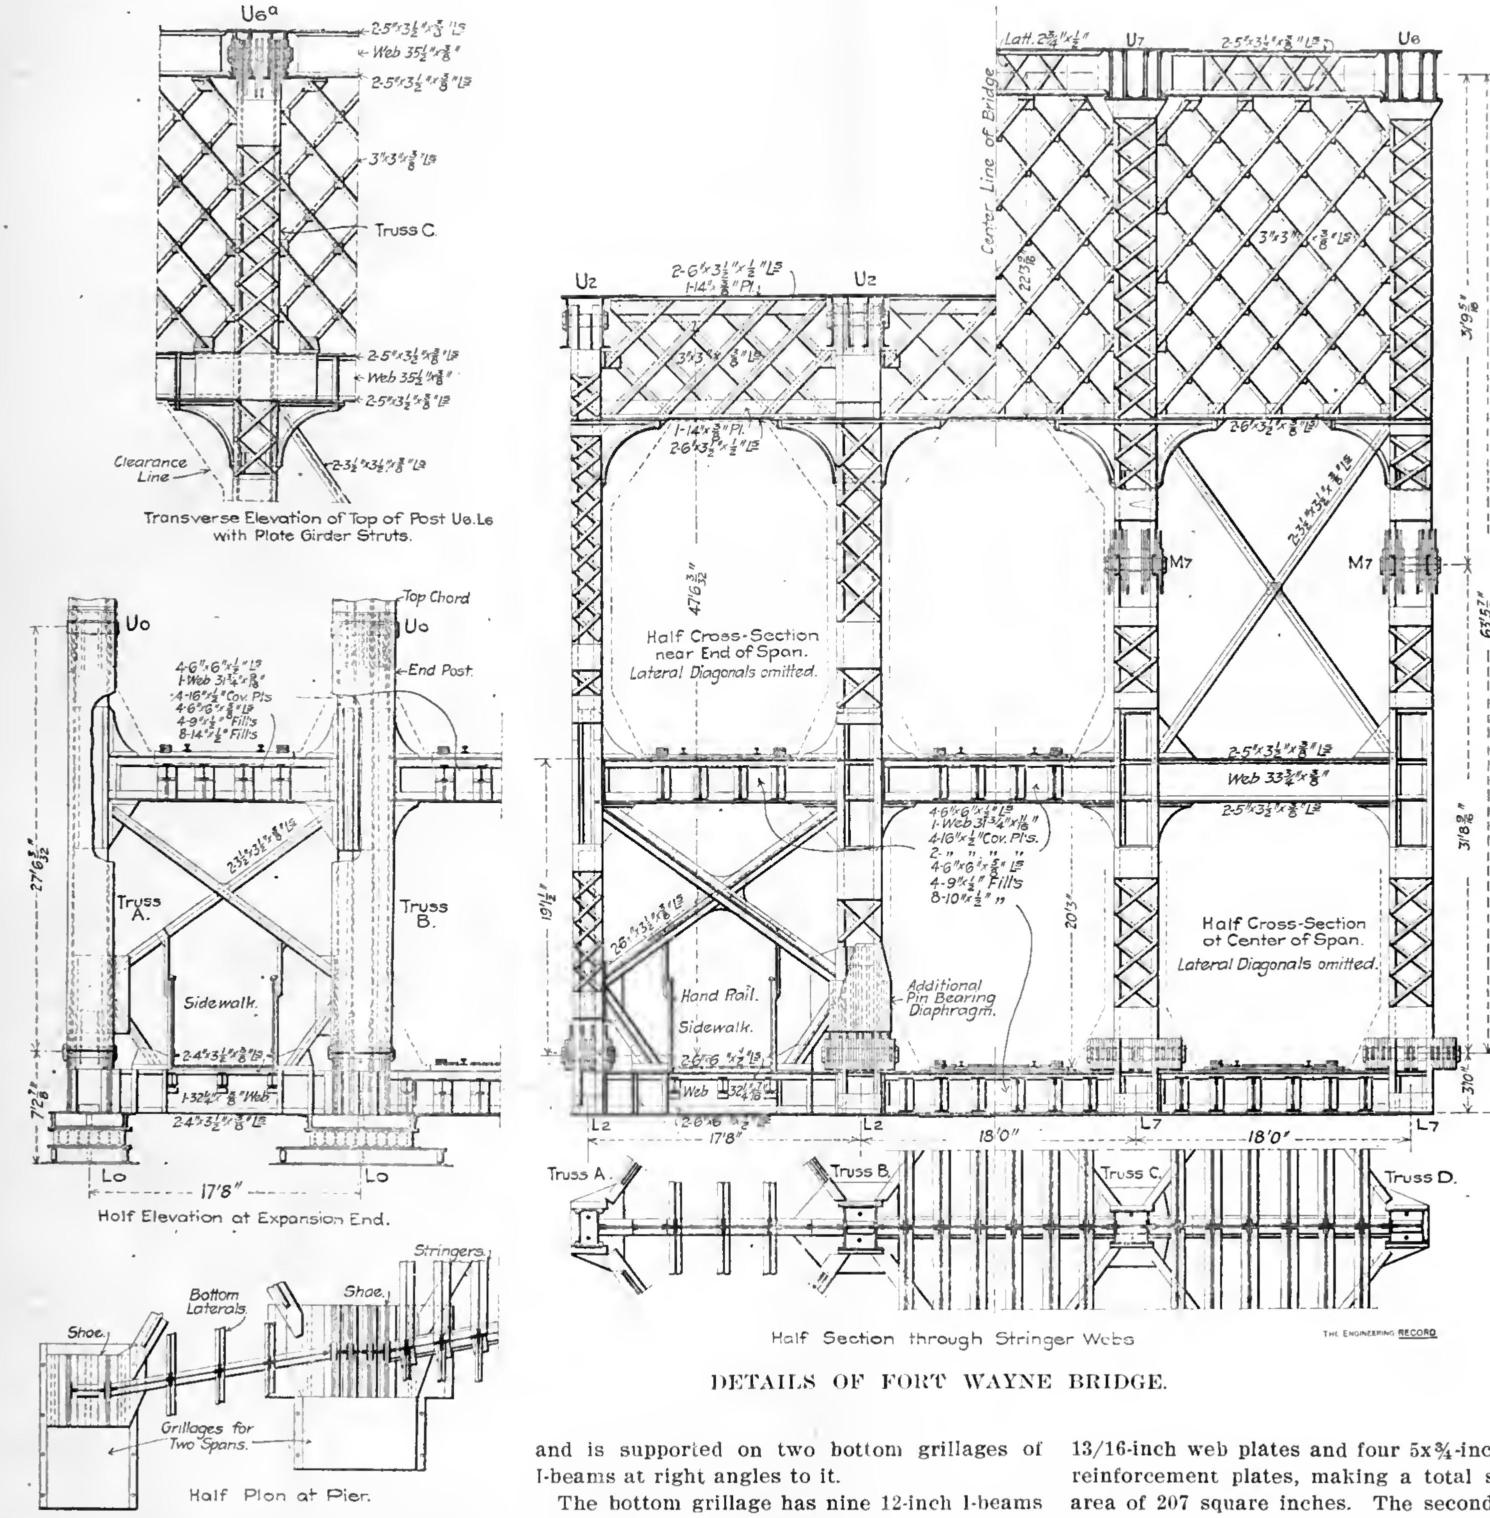
The upper deck floor beams are only about 8 feet in the clear below the end top chord pins so that it is impossible to have portal bracing, the upper tracks are at this point half through and sway bracing is provided by the heavy solid web plate knee braces at the ends of the floor beams, by one panel of transverse X-bracing over the sidewalk and by the depth of the floorbeam connections. The elevation of the end of the span is not symmetrical about its center line beyond the outside of the center truss, B. One outside truss, D, is much heavier than the other outside truss A, and the transverse panel between trusses C and D is different from that between trusses A and B, but the variations correspond to those clearly shown in the intermediate vertical transverse sections.

The top chord pin U1 is only about 18 feet above the top of the upper deck floorbeam and there is no top lateral strut at that point. Top chord pin U2 is about 28 feet above the top of the upper deck floorbeam and the upper transverse bracing there consists of lattice girders about 7 feet deep with T shaped flanges and pairs of diagonal angles with their flanges riveted together at intersections. At U4 and 6 the bracing is similar except that the top and bottom flanges of the transverse lattice girder are replaced by light plate girders as shown in the detached detail of connections to truss. At vertical posts 3-5 and 7 there are diagonal tie connections to the post between the chord pins which are made as shown in the section at U7-L7 and the transverse upper bracing consists of light top struts with I-shaped cross sections and latticing of single 3x3-inch angles between the posts, which is made in each case as deep as the train clearance allows.

The vertical end posts of the center trusses are each made with one 48x½-inch cover plate, four 36x¾-inch web plates, eight 6x4x¾-inch flange angles and four 5x¾-inch flange reinforcement plates. The distance between the inside webs is a little greater than that between them and the outside ones, and their flange angles are riveted on opposite sides, as is shown for the top chord sections to which the end posts correspond, in a manner to make each web with its flanges resemble a Z-bar and promote the facility of shop assembling and riveting. The inner flanges are stayed by ½-inch top and bottom tie plates 51 inches long and by zigzag 5x⅜-inch lattice bars. At the pin bearings each web is reinforced by two full width ¾-inch plates on each side, giving a combined length of 13½ inches bearing for the four supports of each 9-inch pin. The ends of the post are cut to bisect the angles made with the top and bottom chords and are milled to ¼-inch clearance from the center line of the chord pin and have jaw plates merely to hold the members in position, the bearings being made with half holes exclusively.

The webs are connected with horizontal diaphragm plates about 4 feet from the pin centers and by a vertical diaphragm in the plane of the center line of the chord pins which extends from the top of the upper to the bottom of the lower upper deck floorbeam knee brace. The shoe has four webs in the planes of the end to enclose the ends of the rollers. The ends of the rollers are attached by stud bolts to pairs of horizontal bars, the upper one of which is hooked at the ends to engage the lower one and prevent the motion of the rollers beyond a fixed angle. The rollers are grooved for 3¾x ⅝-inch top and bottom center guide bars and rest on fourteen ⅞-inch flat bars 4 and 5 inches wide and 71 inches long on a 71x77x1⅜-inch bed plate, which is riveted across the top flanges of ten 12-inch I-beams 10 feet 1½ inches long. These beams form a top grillage which receives the shoe for the adjacent span in each space. At the fixed end of the span the shoe is the same and the arrangement is like that at the expansion end except that the nest of rollers is replaced by a third or upper grillage made similar to the lower one with nine 10-inch I-beams 5 feet long parallel to those in the bottom grillage and having a cap plate somewhat larger than the base plate of the shoe.

The end section of top chord is made in a two-panel length of nearly 53 feet, and is composed of one 48x½-inch cover plate, eight 6x4x ¾-inch angles, two 36x¾-inch and two 36x



DETAILS OF FORT WAYNE BRIDGE.

post webs and of corresponding thicknesses. They are connected, as shown in the end elevation of the span, by a vertical diaphragm in the plane of the center line of the lower chord pin, and the outside webs are field-riveted to the end vertical web stiffener angles of the end floorbeam. This is seated on the edge of the base plate, which is 71 inches wide, 76½ inches long and is planed to a thickness of 1¼ inches.

At the expansion end of the truss the shoe is seated on thirteen 9-inch segmental rollers and has on each side a 11x⅜-inch vertical plate and is supported on two bottom grillages of I-beams at right angles to it.

The bottom grillage has nine 12-inch I-beams 10½ feet long countersunk-riveted to 72x⅞-inch top and bottom plates 11 and 12 feet long, and has a ⅛-inch lead filler plate between the base plate and the masonry. In both grillages the spaces between the beam webs are closed by 12-inch channels across the ends of the beams with their flanges turned out, and in the same planes as the beam flanges and their webs connected to the webs of the outside beams by short vertical angles. The webs of the grillage beams are connected by a vertical transverse diaphragm on the center line, which consists of a ⅜-inch plate and two 3x3-inch angles 13/16-inch web plates and four 5x¾-inch flange reinforcement plates, making a total sectional area of 207 square inches. The second section of top chord reaches from U2 to U4 and has its section increased 63 square inches by reinforcing the web plates, the thicknesses of the other materials remaining the same. The remainder of the top chord is made in three two-panel sections and has a uniform cross section which is increased 22½ square inches more by thickening the web plates to 4⅜ inches.

Except as noted the construction of the top chord corresponds to that described for the end post, with end transverse diaphragm plates connecting the webs and half-hole bearings for the 9-inch pins at U0-U2-U4 and U6. At each of these points the inclination changes and the joint is protected by a thin splice plate over the top flange cover plates. This plate is extended beyond the flanges to serve as a connection plate for the top lateral rods and transverse bracing and at U3-U4-U5-U6 and U7 there are similar narrower plates riveted to the upper sides of the bottom flanges of the top chord angles to receive the lower flange connections of the I-shaped top lateral struts. There are no top chord pins at U3-U5 and U7 and the tops of the vertical posts are flange riveted to the lower flanges of the top chords.

The transverse strut at U2 is shallow and is not connected to the bottom flange of the top chord. All of the other transverse struts have an intermediate pair of horizontal flange angles which are connected to the lower flange of the top chord. At U4 and U6 the top lateral strut has an I-shaped upper member as deep as the top chord, and flush with it, and a rectangular lower member with top, bottom and side plates, the latter extending across the faces of the vertical posts and riveted to them. The vertical posts U2-L2, U4-L4 and U6-L6 have continuous sections from top to bottom and are made of built channels, latticed and have two 32-inch web plates and four 4x4-inch flange angles.

The intermediate vertical posts are made in two sections each. The lower section is similar to those at L2 L4 and L6, but the upper portions are merely struts to carry the top chords and are made of pairs of 15-inch channels about 2 feet apart back to back and latticed. The feet of all vertical posts project about 4 feet beyond the centers of the lower chord pins to receive the vertical flange connections for the lower deck floorbeams. Vertical diaphragms in the planes of the chord pins connect the post webs above and below the pins and wide horizontal connection plates are riveted to the lower ends of the posts to receive the bottom lateral diagonals. The lower ends of all the vertical posts

DETAILS OF FORT WAYNE BRIDGE.

are similar to that of post U2-L2 except that the latter has the bottom tie plates extended to receive an additional pair of outside vertical diaphragms and there is a center diaphragm, all carried down to the pin center and reinforced with side plates so as to make, with the two main webs, five bearings for the pin. The other vertical posts have only two pin bearings each, one in each main web. All the truss pins are 9 inches in diameter and have shouldered ends with 1-inch washers and octagon nuts. Pin L7 has a 74-inch grip and carries twenty 10x2⅜-inch eyebars.

The outside trusses resemble the inside ones except that they are lighter and that the lateral and transverse member connections are different on account of the arrangement of the floor systems, but the details are substantially similar and are varied only as necessary on account of their relative functions and positions. The top chord is 36 inches wide and 36 inches deep and has only two webs, throughout, but these webs are reinforced in six panels. The end two panels of bottom chord are made with pairs of 10x1 3/16-inch bars which have a 3½x3½-inch angle riveted to the inside of each, from end to end, to serve as a connection for tie plates and lattice bars by which they are braced together.

This span weighs about 3,000 tons and was designed and constructed under direction of Mr. Thomas Rodd, chief engineer, and Mr. J. C. Bland, engineer of bridges for the Pennsylvania Lines West of Pittsburg. The inspection was performed by the railroad company's force under Mr. C. P. B. Buchanan, inspector of bridges. The riveted members were built at the Pencoyd plant, and bars, pins and rods at the Keystone plant of the American Bridge Co., Mr. Paul L. Wolfel, chief engineer. The erection was done under direction of Mr. S. P. Mitchell, chief engineer and Mr. H. A. Green, assistant engineer and superintendent of erection for the western district.

(To be Continued.)

The Cement and Concrete Exhibits at the Düsseldorf Exhibition furnish excellent examples of the admirable results obtainable with skilled workmanship and good materials properly used. These exhibits are grouped in and about a large terrace on the bank of the Rhine. At the head is a large fountain and basin, adorned with concrete sculptural work and on each flank is a lofty column. The steps, balustrades and arcades of the terrace are all concrete, and one of the neighboring buildings is a concrete structure resembling in exterior appearance some of the city halls in small German towns. The columns have a total height of 114¾ feet. The foundations extend 18 feet below the surface and are made of 1 part cement to 10 parts gravel, with a grillage of steel beams; the foundations are square and measure 42.7 feet on a side. The rather elaborately ornamented pedestals are 40.3 feet high. The shafts are 52.1 feet high, 7.4 feet in diameter at the base and 6.2 feet at the top. The bottom portion, with ornamental reliefs, is a ring of rammed 1:5 concrete while above the work is a succession of rings of similar concrete with a 1:2 plain mortar facing; the rings are about 3.2 feet high, and each has six vertical and three horizontal steel rods as reinforcement. The shaft has an ornamental capital with a metal dome surmounted by a large concrete figure. Another special feature of the exhibits is a 1:4:4 concrete bridge of 98.4 feet span, and but 6.56 feet rise. The arch is 2.3 feet thick at the springing and 2.13 feet at the crown, and showed no appreciable deflection under a load of over 90 pounds per square foot.

A Concrete-Steel Sewer.

A contract was awarded a short time ago by the Board of Public Works of Harrisburg, Pa., for the construction of a concrete-steel sewer, which is among the most interesting works of the kind recently designed. The plans and specifications for the work were prepared by Mr. James H. Fuertes, M. Am. Soc. C. E., consulting engineer to the Board, and the construction will be under his general supervision. In a general way the problem was the design of a sewer to intercept the ordinary flow of a system of combined sewers in a district lying on both sides of a small stream, Paxton Creek, which has been receiving these liquids directly. The creek now receives about twenty times as much sewage as should be discharged into it, and consequently during dry weather it is extremely offensive.

The interceptor will be large enough to receive the total flow, during ordinary rainstorms, of all the sewers to be connected with it; that is, the flow from storms of ¼-inch or less per hour. As about 95 per cent. of the rainstorms have these low rates, the overflows will discharge sewage into the creek only at rare intervals. About twenty per cent. of the annual precipitation falls in storms of high rate for short periods of time, and during such storms, the mixed sewage and street water will overflow into the creek, the creek being then at a high stage. The discharge of sewage at the overflows at such times will be unobjectionable for the reason that the heavy discharges at the overflows will cease before the creek floods run out, and therefore as the creek subsides all traces of the dilute sewage discharged at the overflows will be carried away.

The engineering difficulties were increased by the presence of considerable ground water in the gravel formation in which the construction must be done, and by the necessity of using extremely flat grades in order to avoid prohibitive excavation and pumping. The grade problem has been overcome by making the sewer somewhat larger than necessary for the interception of the dry weather sewage alone and by forming a connection between the upper end of the interceptor and the creek, where automatic regulating gates have been provided which will admit during dry weather enough creek water to the conduit to keep the flow in all its parts at a self-flushing velocity. During rainstorms when the lateral sewers are discharging large quantities of both sewage and street water into the interceptor, a float will rise, closing the valve and thus shutting out the creek water.

The form of this regulating chamber is shown in the accompanying drawings. There will be two sets of three 12-inch vitrified pipes laid through the concrete head wall to serve as inlets for the creek water, one set 4 feet higher than the other. Before entering the regulating chamber proper the water will pass through a large rectangular silt basin in order to allow as little suspended matter as possible to get into the sewer. This silt basin in largest internal dimensions will be 20x8 feet and 12 feet deep. A grating of steel bars spaced 1¼ inches apart will prevent large floating articles from entering the inner chamber. After being roughly screened in this manner, the water will pass through the rectangular cast iron orifice tube into the regulating chamber proper.

The valve regulating the quantity of creek water allowed to enter the sewer is in general principle the usual form adopted for such purposes, the opening of the valve being automatically controlled by a galvanized iron float. As the float rises the rotating valve closes. The chief difficulty with such valves heretofore has been in getting the valve to slide smoothly and accurately on its seat, some very careful adjustment and machining being usually necessary to accomplish this. In the design here adopted a great deal of this is avoided. The rotating arm will be attached to the concrete wall of the float well by means of a short length of angle iron, the holes through which it is bolted to the latter being slotted so as to permit a vertical adjustment. The horizontal leg of this angle, and the flanges of the trunnions carrying the rotating arm will be slotted to allow a play horizontally in two directions. By this simple arrangement, when the valve is first installed it can be loosely bolted in place, adjusted by means of the slotted holes until it works perfectly, and then securely bolted to its final position.

The float well is to be connected to the sewer by a 4-inch vitrified pipe extending underneath the invert about 10 feet down the sewer, where the opening will be covered by a cast iron grating cemented into the bell of the pipe. All parts of the valve with its rotating arm and lever will be of cast iron except the face of the valve and all wearing parts, which will be bronze. The galvanized iron float is 11x24 inches and 9 inches deep. With the exception of the brick manholes this whole construction of inlet and regulating chamber at the head of the interceptor will be of 1 : 2½ : 4½ concrete, reinforced as shown in the illustrations by 3-inch mesh No. 10 expanded metal.

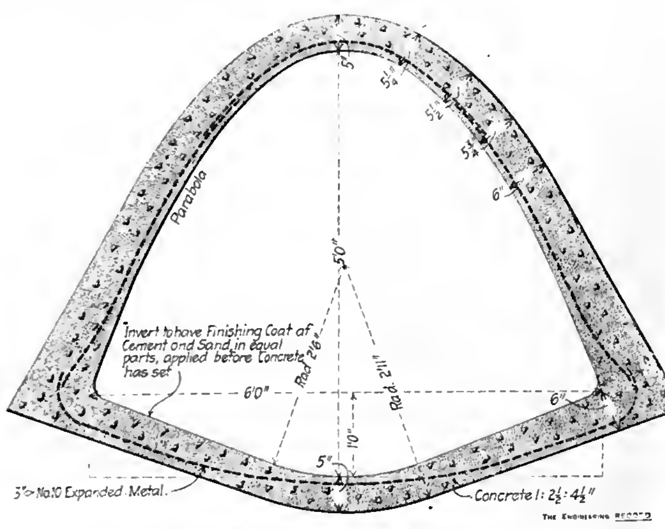
The contract for this work includes 6,780 feet of the 5-foot parabolic sewer, 7,635 feet of the 4-foot parabolic sewer and 385 feet of a 5-foot rectangular section where the interceptor passes longitudinally under the tracks of the Philadelphia & Reading Railway Company. The design of the main intercepting sewer, although somewhat unusual in section, is nevertheless easy of construction. The crown of the arch is a simple parabola. The invert is rounded in the middle, and for the 5-foot section has an inside radius of 2 feet 6 inches, the rest of the invert being tangent to this and extending out to points on either side 3 feet from the center line and 1 foot above the bottom, the corners being slightly rounded to connect smoothly with the arch. For the 4-foot section the radius of the invert is 2 feet and the total width to the ends of the tangents, 4 feet 9.4 inches, the height of these points above the bottom of the invert being 9.4 inches.

The same thickness of concrete will be used for both the 4-foot and the 5-foot sections. In the invert it increases from 5 inches at the center to 6 inches at the sides, while in the arch it varies from 5 inches at the crown to about 9 inches at the base. The sections being of abundant strength to support the vertical loads which will come upon the sewers, it was not considered necessary to place the expanded metal along the exact lines of greatest tension. It may be stated that throughout the designs, the use of expanded metal was so arranged that there would be no waste—either whole or half sheets being used in all cases. An interesting peculiarity in regard to the section adopted for this sewer is the fact that it will give practically the same discharge as a circular sewer of the corresponding diameter. More exactly stated, the 5-foot parabolic section running full will discharge 54 cubic feet per second, while a 5-foot circular sewer of the same material under the same conditions of grade would discharge about 3.7 per cent. more, or 56 cubic feet per second.

Where the interceptor passes under the tracks of the Philadelphia & Reading Railway, for a distance of 385 feet, a rectangular section will be substituted for the standard parabolic section. It will have an inside width of 5 feet, and a height, from invert to springing line of roof arches of 4 feet. The shape of the invert will be the same as that of the regular parabolic section. The side walls will be of concrete 12 inches thick and without reinforcement by expanded metal. The roof of this section will consist of 8-inch I-beams running crosswise of the sewer and spaced 3 feet apart, between which concrete arches with 3¾ inches rise will be laid, thus inclosing all parts of the beams except the lower flanges, which will be surrounded with heavy wire lathing and plastered with 1 to 1 cement mortar. The beams will be 6 feet 4 inches long over all, resting on 7/16-inch steel bed plates 8 inches wide and 12 inches long, carefully bedded into the top of the side walls at the proper height. The top of the concrete roof will be 10 inches above the crowns of the arches.

The concrete for all the main parts of the interceptor will be a 1 : 2½ : 4½ mixture. The specifications call for a careful storage of the cement, which is to be of an approved brand of American Portland, in a building sufficiently large so that different lots can be kept separate, and no cement is to be used which has not been kept in the store house for at least two weeks. The building is to be provided with suitable scales for weighing, and an inclosed space for cement testing, this space to be properly lighted and maintained during the cold weather at a temperature of from 60 to 70 degrees.

As it is important that the cement to be used on this work should be of the best, it is required to be of a uniform color, fresh and



Section of Five-Foot Interceptor.

ground so that not more than 10 per cent. by weight will be left on a sieve of 100 meshes per inch. Its specific gravity must be at least 3.1. Round pats of neat cement 3 inches in diameter and ½ inch thick at the center, tapering to a feather edge, must show none of the usual signs of unsoundness after being left in air or water at ordinary temperatures for 28 days. The accompanying table shows the ultimate strength which must be developed by briquettes of one square inch section, as determined from an average of five specimens.

Required Strength of Briquettes, pounds per square inch.

	1 :3		Neat		
Age, days....	7	28	1	7	28
Strength	150	200	170	450	550

The specifications for sand state that it shall be sharp, sufficiently coarse, and shall not contain more than 3 per cent. by weight of loam, clay, coal and perishable matter. This provision is especially necessary in the vicinity of Harrisburg because much of the sand used there is taken from the river bed and contains at times very large quantities of fine coal washed from collieries.

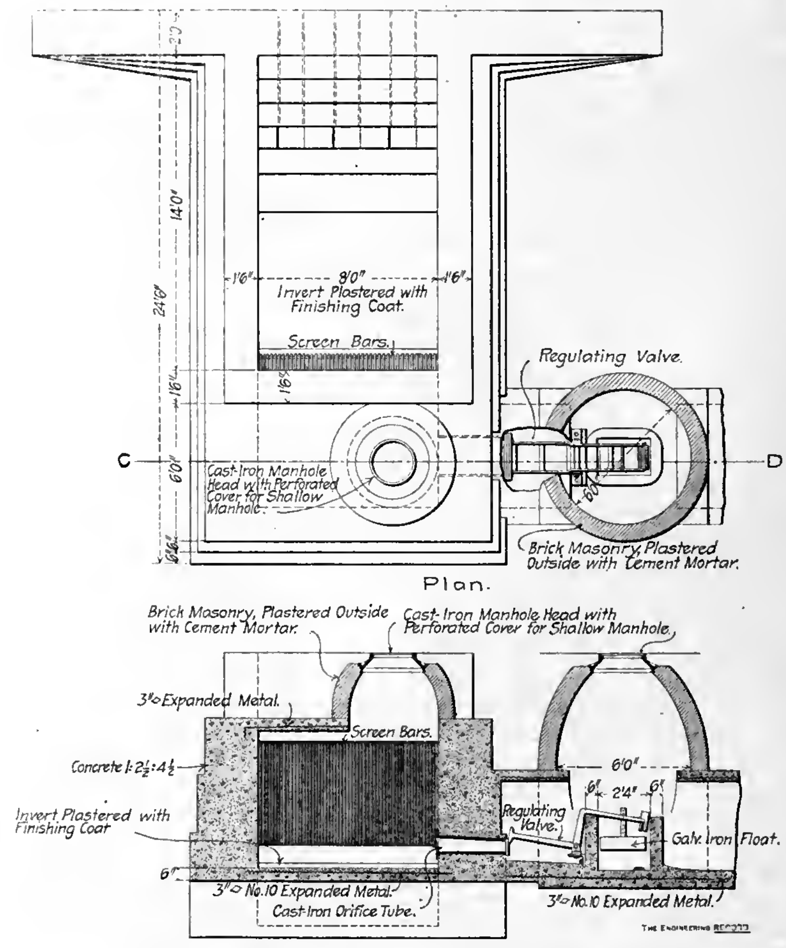
Either gravel or broken stone or a mixture of both may be used as the ballast for the concrete. The stone must be broken to pass a 1½-inch ring, and all dust and fine particles are to be screened out. The materials are to be graded from fine to coarse and will be mixed so as to give as uniform a proportion of voids to be filled by mortar as possible. If deemed necessary by the engineer the ballast must be washed or screened to free it from dirt, clay, coal, shale or other improper substances.

Standard boxes are to be provided for measuring the exact proportions of the ingredients of the concrete for each batch before placing in the mixers. The concrete is to be thoroughly mixed, and wet enough to permit satisfactory tamping. In laying concrete in walls the layers will be from 4 to 9 inches thick. In other places the thickness of the layers will depend on the character of the work in hand. As the concrete is placed in the molds it is to be tamped with suitable rammers until a film of water appears on the surface and all the interstices between the stones are thoroughly filled with mortar. Special tools will be used and special care taken to insure the thorough tamping of the concrete where it is in contact with the surfaces of the centers.

In joining new work to that which has already set, or partially set, the edge of the old portion is to be brushed thoroughly clean, broken down if required, washed, and slushed with neat cement. The invert of the interceptor is to have throughout its whole length a finishing coat of mortar consisting of one part cement to one part sand, which coat is to be carefully applied with trowels before the concrete has set, and after the concrete surface has been brushed clean and thoroughly wetted. No walking will be permitted on the invert after the application of this finishing coat until it has thoroughly set. After the removal of the arch centers the junction of the side walls with the invert is to be carefully trimmed to a smooth, rounded surface. The inverts on the bottoms of manholes, especially those at the ends of the inverted syphons, will receive particular attention so as to preserve the continuity of flow. The respective channels will gradually merge into one, leaving no pockets to cause eddies or retain deposits.

The expanded metal used is to be cut and bent to the proper shapes before being placed in position. Where sheets meet on either horizontal or vertical seams, they must lap at least two inches. The metal will be held firmly in place by blocking while the concrete is being tamped around it.

In order to connect the existing sewers on the further side of Paxton Creek with the interceptor it will be necessary to construct several inverted syphons. The connections at both ends of these are shown in detail in the accom-



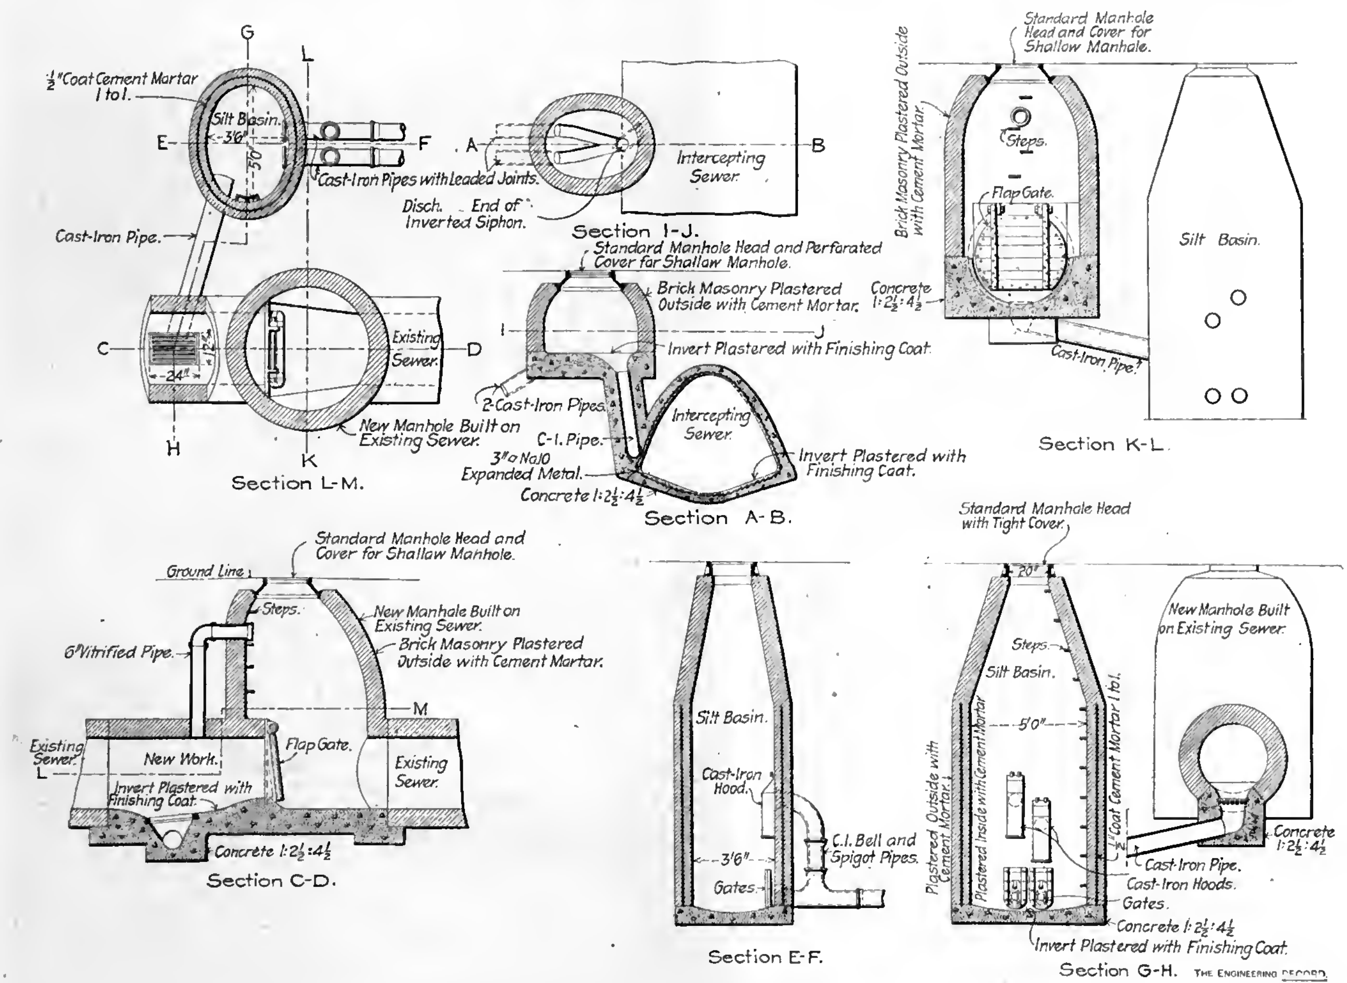
Regulating Chamber at Head of Interceptor.

panying cuts. At the inlet ends of each of these syphons a section of the existing sewer will be taken out sufficiently long to permit the construction of a new manhole, sump and connection with a silt basin. According to the new arrangement, the ordinary flow of house sewage as it comes down the old sewer will flow down a cast-iron pipe leading from the sump in the sewer invert to the silt basin, which will be 5x3½ feet in plan and of a depth depending upon the conditions encountered in each case. The two outlets from this silt basin will be 3½ and 4½ feet from the bottom, and the sewage will flow through these and down under the creek in two lines of cast iron pipe, rising at the other side into a shallow manhole from which it will be discharged into the interceptor.

As the sewers are built on the combined system, the entrances to these inverted syphons were designed to permit the greater part of the storm water to pass directly into the creek through the old outlets, flap gates being provided just beyond the sumps to prevent back water in times of flood from flooding out the interceptor. These flap gates are to be made of cypress lumber in order to secure lightness, and faced with rings of steel where they bear upon the cast iron frames. Each gate will be hung on two wrought iron strap hinges extending the entire width of the gate and sunk into the under side of it. On the outside of the gate two wrought iron straps will be placed and securely bolted through the gate to the hinges. After the gate has been hung and closed the face joint is to be made by pouring the groove left in the face of the frame for that purpose full of lead.

The sump at the intake end of the inverted syphons, through which the sewage will enter the silt basin, will be protected by a cast iron grating, and the diameters of the pipes leading from these sumps will of course be different for each case. The walls of the silt basins will be of brickwork 8½ inches thick, and up to 2 feet above the crown of the existing sewer the walls will consist of two separate rings with a ½-inch layer of 1 : 1 cement mortar between.

The outlets from the silt basins will be provided with cast iron hoods to prevent floating matters from getting into the syphons, and gates at the bottoms of the basins will lead directly into the syphons at the lowest level for flushing purposes. The two pipes under the creek will unite at the discharge end in a manhole from which the sewage will flow down a cast iron pipe into the interceptor. The sizes of the syphon pipes, and the differences in elevation between their intake and outlet ends have been proportioned in each case, so that when the sewers are discharging at their maximum capacity, each syphon will take to the interceptor its quota of flow, the balance going directly to the creek through the overflow.



DETAILS AT ENDS OF INVERTED SY PHONS.

It may be noted here that the forms for the proposal, specifications, contract, and bond under which this work is to be done are printed in a carefully arranged and well indexed pamphlet so that any doubtful points may be quickly referred to by the contractor or the engineer. A clause in the contract providing for a penalty in case of failure to complete the work on time, and an equal bonus for completion of the work ahead of time, deserves special notice and is quoted in full.

"In consideration of the agreement of the party of the first part to grant the contractor extensions of time for the completion of this contract, and in consideration of the material losses and damages that would accrue to the party of the first part, on the failure of the contractor to fully complete the works within the time specified in this agreement, and of the fact that the actual value of such damages would be difficult of ascertainment, it is hereby mutually agreed that there shall be deducted from the amount due the contractor for work done and materials furnished under this contract \$50 per day as just and liquidated damages for each and every day required (except Sundays and legal holidays) after the expiration of the extended time above mentioned, for the completion of the work; and further, in consideration of the material benefits which would accrue to the party of the first part should the contractor be able to complete the work before the expiration of the time limit above mentioned it is hereby mutually agreed that there shall be paid to the contractor \$50 per day (providing he completes the work under this contract before the expiration of the time limit above mentioned) for each and every day (except Sundays and legal holidays) between the date of the completion of the work and the expiration of the said extended time, as provided for by this contract. The date of the completion of the work is mutually understood to be the date upon which the engineer shall transmit to the contractor the certificate of acceptance."

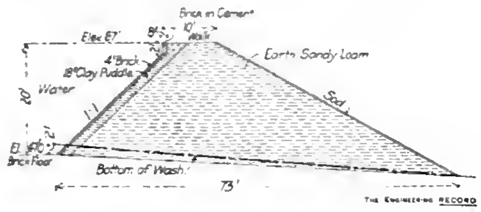
The contractor for the work is Mr. S. M. Neff, of New York, whose prices for the 5 and 4-foot sections were \$9.80 and \$8.95, respectively. The contract price for the total work, which includes a 36-inch outfall into the Susquehanna River of vitrified and cast-iron pipes, was \$167,-227. The date set for its completion is October 31, 1903.

A Reservoir Break at Camden, N. J.

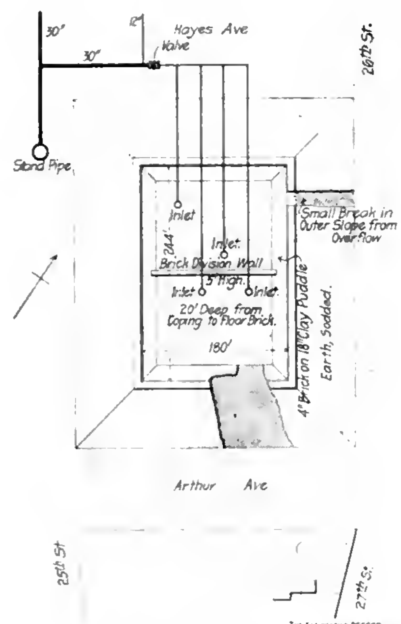
When the city of Camden, N. J., took over, about thirty years ago, the property of a private water company which had previously supplied its citizens, it became the possessor of a service reservoir built some time before by Henry Allen. It is located on a sandy hill about 47 feet above the high-water level of the Delaware River, and its dimensions on the inside of the coping are about 244 feet length, 180 feet width, and 20 feet depth. A low division wall separates the basin into two sections, but when the water is over 5 feet deep the reservoir is practically a single basin. The original capacity was 4,500,000 gallons, but this was increased later to 5,250,000 gallons. Water is delivered to the basin through four inlet pipes and a by-pass from a main supplying a nearby standpipe. South of the reservoir, across Arthur avenue, is another standpipe belonging to the Stockton Water Company.

The embankment seems to be made of sandy loam, and measures about 70 feet on the base and 10 feet on the top. It is lined with 18 to 24 inches of stiff clay, and this clay is covered with one layer of common brick set on edge and apparently grouted at one time, although nothing but mud remains in many of the joints. There was no core wall of any sort. About fifteen years ago, when the embankment was slightly raised, a brick wall was added to the top of the lining; this was not backed with puddle, as shown erroneously in the diagram.

The reservoir is now employed only during repairs to the pumping plant of the driven-well system, described in The Engineering Record of May 6, 1899. One of the pumps was overhauled recently, and the reservoir was employed to hold the excess of the night pumpage for use during the daytime. When the pump was again in service, the chief engineer at the station personally ordered the watchmen to close the valves controlling the flow to the basin. Whether they were not fully closed or whether, after being shut, some one opened one of them, seems to be in dispute. There can be no question, however, that water entered the reservoir during the night of October 1, for about 4 o'clock in the morning of October 2 the embankment at the southeast corner gave way.



CROSS-SECTION OF EMBANKMENT.



POSITION OF THE BREAK.

Only a part of the piping is shown in this diagram. There are two cross-connected 30-inch pipes running to the standpipe. One of them has a 30-inch connection with gate valve to the reservoir and was used as an overflow from about 1871 to about 1890, when the standpipe was built; it was then used as an inlet and the original 12-inch force main employed as a drain pipe, for it has a blow-off some distance from the reservoir which adapts it to the purpose. There is a 30-inch branch from this 12-inch main and from the second 30-inch main to the standpipe, with a valve in the position shown in the diagram. This valve was the one that was open.

The appearance of the break, which is 69 feet wide on the coping line, and about 30 feet at the bottom, is fully shown in the accompanying illustrations. A smaller overflow occurred on the east bank.

On three sides the reservoir is quite closely surrounded with frame houses. Directly opposite and only 60 feet distant from the break, is the standpipe of the Stockton Water Co., which divided the outpouring flood into two main streams. These swept down the streets to low ground, where the general repair shops of the Amboy Division of the Pennsylvania Railroad are located; these were flooded one or two feet and it was necessary to shut them down half a day to clean out the mud and water. Numerous fences were carried away and several cellars were filled with water. The division of the water into several streams spread over a uniformly sloping hillside prevented any serious damage, while the early hour of the accident prevented loss of life, which would probably have occurred if people had been on the streets.

It has been claimed locally that the accident was due to a high wind, which caused waves heavy enough to break over the embankment. This seems incredible in view of two facts. First, the basin is too small for wave action to amount to anything. Second, the main overflow occurred at a point where the coping wall was 2 to 6 inches lower than elsewhere, but there was also enough overflow at a point 200 feet away to wash out the sod and about 50 cartloads of the outer slope. These two independent overflows indicate that the basin was overfilled and water was pumped into it continuously; in fact, one of the valves supposed to have been shut, was found open after the accident.

The reservoir seems to have been a fairly safe structure, barring the absence of a core wall, which would probably have saved it. It had been emptied and filled a number of times without any weakness being detected in the embankment. Its failure can therefore be attributed to the same cause as that of the Grand Rapids reservoir, described in The Engineering Record of July 14, 1900, namely, overfilling. It is to be hoped that the lesson of these failures will be appreciated by Water Boards having basins similarly neglected, for a reservoir without any high-water alarm connection with the pumping station supplying it, or an equivalent safety device, cannot be considered properly cared for. It makes little difference whether the reservoir is used once a year or every day; it is a source of danger unless there is some safeguard against overfilling it. The gauge on the force mains at the pumping station is too unreliable. A special lesson of the Camden accident is the necessity of keeping valves safe from the possibility of manipulation by persons unconnected with the water department.

VIEW OF BREAK FROM INSIDE THE RESERVOIR.
The standpipe belongs to the Stockton Water Company and parted the flood as it issued from the break.

VIEW OF BREAK FROM OUTSIDE THE RESERVOIR.
The clay lining is still in place under the three boys.

Direct-Current Transmission of 5,000-horsepower at 23,000 volts is effected by the city of Lausanne, Switzerland, from a water-power plant near St. Maurice, 35 miles distant. The power plant comprises five main generating units, each consisting of two 500-horse-power dynamos driven by a 1,000-horse-power turbine, the dynamos all connected electrically in series. Each turbine is 3.28 feet in diameter and operates under a head of 105 to 111.5 feet, with a flow of 110 cubic feet of water per second and at a speed of 300 revolutions per minute.

Sewer Maintenance; Under Whose Supervision and Why?

Extracts from a paper presented to the American Society of Municipal Improvements by John H. Emigh. City Engineer, North Adams, Mass.

The object to be sought in the maintenance of sewers is to provide at all times for an unobstructed flow of the sewage, to prevent solid matter from lodging along the main line or its laterals, and to secure good ventilation. Neglect of the first is likely to result in a set-back into house fixtures and an overflow at their lowest outlet. Neglect of the second leads to decomposition and the attendant offensive or dangerous gases; and of the third to an increased pressure of those gases until they are forced through the house traps and into residences. Only about 1 ounce pressure per square inch is sufficient to force the seal of an ordinary house trap; and I suppose that in every city there are many residences whose plumbing is of the older methods and is practically without ventilation. This means that when sewer gas has once entered the house it has no means of escape other than through fixtures into the rooms.

The first requisite for successful maintenance is good construction. This consists in having proper foundation, thorough tamping about the body of pipe in back-filling, imperviousness of joints, uniformity of grade and good alignment between manholes or lantern-holes, easy curves and smooth flow surfaces at the manholes, frequent Y branches for connecting house laterals, all with a plan and profile containing a clear and reliable record of location, depth, grade, position of Y's and other sewer adjuncts and sometimes the proximity of water or gas pipes. The designer and the inspector have always to contend against a disposition towards cheap construction—a tendency to use an easy way around difficulties because, no doubt, of the belief that, when covered, a critic's eye may not see the faults, and, too, of the possibility that he who causes them may not have to suffer from their results.

The ideal conditions that should be striven for are those that will cause all matter entering the sewer to be delivered so quickly at the final outfall that there has been no time for decomposition. These conditions very rarely if ever exist in any extended system.

The second requisite for good maintenance is systematic vigilance. It is injudicious, expensive and the cause of much annoyance or damage to neglect the sewer until it has become stopped, and the only way to avoid such a condition is to take proper precautionary measures which should include regular examinations at not too great intervals. There is probably no more efficient and economical method of keeping the sewer clean than frequent flushing.

Manhole covers should be placed flush with the surface of the street both for convenience and as a means of ventilation.

Laterals entering from factories and similar buildings should be provided with some arrangement for keeping from the sewer anything that is likely to form in it an obstruction. A piece of cloth, 20 yards in length, late from the loom, or a piece of 4-inch belting 10 feet long found within the sewer are indications that some people are indiscreet. I know of no better provision for such places than a manhole near the outside of the building, its bottom made slightly below the outlet, enough so that the discharge is made first into a quarter-turn, opening downward. This works very well, it keeps the outlet opening always submerged and acts as a trap. It is objectionable in that matter accumulates in the manhole and may need occasional cleaning out, but it is probably less objectionable than the usual form of connection.

In a combined system or in the surface water sewer of a separate system there is frequently an accumulation of gravel or street dirt that greatly reduces the capacity of the sewer or stops it entirely. Too often this condition is not known until there is a heavy shower and the sewer refuses to do its work. There is great liability to trouble of this sort wherever the higher parts of the system are in dirt roads and along steep hills. The strong wash along street surfaces carries gravel and sometimes stone beyond the catch-basin trap into the sewer, thence to the flat grades where the reduced velocity allows them to stop and accumulate. These places of accumulation should be watched and frequently attended to. If taken in time the obstructions may generally be removed by a strong stream of water obtained by a direct connection with the street main as already described or through a line of hose attached to the nearest hydrant. Sometimes a heavy chain with knots in it may be drawn either way in the sewer, thus loosening the material that has been deposited. Much of this may be taken from the next manhole below if a shoveler is kept constantly at work and the water is made to flow over a blocking which covers the lower half of the outlet of that manhole. When the sewer is large enough so that men may conveniently work inside it becomes simply a case of shoveling the material and conveying it out by an arrangement that best suits the conditions.

When the sewer is entirely stopped the problem is one of greater difficulty. No rule can be set down for its treatment and the solution must be as the case requires even to the taking up of a portion of the street, if necessary. Ordinarily the obstruction must be worked at from the manhole next below. Sometimes a sewer may be probed for 200 or 300 feet by a rod made up of sections, either in wood or iron, each 3 or 4 feet in length, joined at their ends by Felton's improved coupling. These constitute a convenient arrangement and may accomplish the purpose in small sewers of from 8 to 12 inches in diameter. Sections made of wood are light and easily carried about. A stronger rod and one capable of greater length may be made of ½ or ⅝ inch iron pipe, cut in sections of the same length as above described and fastened together by screw couplings. This with hook or claw at the end is likely to accomplish much better work than the other. It is slower to make up and much heavier to handle than the one made of wooden sections.

A water-jet may, at times, be very useful. Perhaps a mirror may be made to throw sunlight into the sewer and help to determine the location and character of the obstruction.

Whatever the difficulty I believe it is well to keep a tabulated record of the date, character, location, cost of removal and such other explanations as may seem wise, as well as a record of the flushings. They are convenient for reference, they explain accounts, and are likely to be of use to the successor in office.

Cleaning catch-basins is an important item of maintenance and one of the most expensive unless well managed. Hardly another bit of work has so strong a tendency to slowness on the part of the workmen. As suggestive of a good method now being used, I take the liberty to quote from a letter recently received on this subject as follows:

"All catch-basins are numbered and are regularly inspected by a man who records the depth of dirt in each. From this record lists of the basins needing cleaning are made out and given to the cleaners, with the route they are expected to follow. The cleaners make a return each day of the basins cleaned and of the number of loads taken from each. From these returns we obtain a check upon the work each cleaner is doing and are able to obtain the cost per cubic yard of the material removed from the basins.

"When the cost per cubic yard runs above normal figures we detect it and at once investigate the cause. By the adoption of this method we have succeeded in greatly reducing the cost of cleaning (I believe it to be capable of still further reduction), and obtain a record of each basin which is valuable in case of complaints.

"By this method the men do not stop to clean a basin that has 3 feet of water and only 1 foot of dirt but attend to only those basins which need attention. They do not have to be accompanied by a foreman, as the returns show the amount of work done each day."

The same writer says that the cost per cubic yard for removing and hauling away was $0.665 in the year 1899 and was $0.68 in the year 1900. The haul was probably about 2,000 feet and the difference in cost probably due to the difference in length of haul.

The manner of connecting house laterals with pipe sewers is a matter that belongs frequently to maintenance and is of considerable importance, especially if no Y has been provided, in construction, for the connection. Cutting an opening through the side of the sewer should not be allowed. Removing a length of pipe and replacing it by another that contains a Y branch is objectionable because with any considerable run in the sewer or with the run turned on before the cement has had time to set is very likely to result in leaky joints. Taking up three or four lengths of the old pipe in order to not be obliged to cut away any of the bells in relaying is open to the same objection. The writer believes there is no better method than to excavate entirely around the pipe and encase it in brick masonry or concrete nearly to its top, then carefully cut the hole in the top of the sewer and join the lateral to this by a quarter of an eighth bend, making sure that none of the smaller pipe extends inside the shell of the larger pipe; then continue the masonry to cover the joint thus made. This, if properly done, does not weaken the sewer, nor cause it to leak or become rough on the inside. It may reduce somewhat the grade of the lateral but this it should be able to stand or the elevation of the fixture is dangerously close to that of the sewer.

The laying of house laterals is probably more faulty than that of any other part of the system and is, in consequence, the place of more stoppages. They are frequently laid without supervision, by contract and at the lowest price. There is no reason why these should not be placed, by the city, under the same supervision and restrictions as other parts of construction. A license to the drain layer does not insure good results.

The third requisite for successful sewer maintenance is a right kind of man to do the work. If the system is large divide it into sections and select a man for each, all subject to the direction of the head of the department. The selection should not be made in accordance with the policy that anything will do. The man should be intelligent, reliable, and have a reasonable degree of common sense. His work is not of an agreeable character but he should have an interest in it and should take pride in doing it well. Very much of his method and what he does may be hidden, so he must have an ability to see what needs to be done and be honest in carrying out instructions. He must, like every other man, in order to do good work, feel that he has a responsibility and is being trusted. The one under whom he works must show that good service is appreciated and must, as far as possible, make use of the subordinate's judgment. Respect him and let him know it. If he is unworthy of this he should not have the place. Make him feel and know there is as much dignity and honor in well filling his position as there is in filling any other. This, it seems to me, is the only way to get from a man the best that is in him.

The question of maintaining ventilation is a somewhat difficult one, especially in dirt roads. In paved streets a perforated manhole cover seems reasonably satisfactory if the perforations are kept open, but in the dirt road they are very liable to become stopped: yet there seems to be no better method even here. To obtain good results they must be watched and frequently cleaned. A 4-inch pipe connected with the drain just outside the running trap of each house and running to a point above the roof no doubt provides a first class ventilation for the sewer and protects the house from sewer gas as much as is possible. Its expense makes it somewhat objectionable and if carried up in a conspicuous place it is unsightly. The necessity of good ventilation has already been mentioned.

Under whose supervision should the maintenance of sewers be placed? This can not be answered by the man's municipal title. He should not only be competent to design and construct but he should have had experience in it. A knowledge of the theoretical and the practical are most desirable qualifications for supervision of maintenance. He should not only be capable of reading drawings but of making them. He should know when to make them and of what. He should be most familiar with the system and should be able to decide quickly what should be done for the difficulties that are likely to arise. He should attend to a clear and concise record of the work done kept in a form convenient for reference. Finally he should be able to establish a cooperation with his men and a condition of mutual confidence. At the same time he must be master of the situation and must see that his orders are obeyed.

Residential Septic Tanks.

Paper presented by Burton J. Ashley to the American Society of Municipal Improvements.

In the year 1890 the writer moved into one of the suburbs of the city of Chicago, where there was neither water nor sewer service. To the securing of a good sanitary condition of things on and about the premises, we at once directed our attention. The dwelling which was to be occupied had been provided in its construction with all the modern improvements so far as the plumbing was concerned, but these appliances could in no way be of any use without the accessibility of such services as have been mentioned. Water service was therefore provided by pumping storm water from a cistern to a tank which was constructed in the attic.

Sewer service was secured through the construction of a 4-inch vitrified pipe main which emptied into the vault of an outdoor privy which had been previously constructed as a primary expedient, and which in turn was provided with a common 4-inch tile outlet leading to a small slough about 200 feet away. This privy vault was afterwards cut out of the course and the 4-inch drain made to run continuously from near the house to the end of its outlet. Near the house and on the line of this 4-inch sewer there had been constructed a catchbasin 4 feet deep and 3 feet square, with about 2 feet of this unsuspicious though worthy receptacle lying below a trapped outlet. The inlet was not trapped and therefore found ventilation through the soil pipe above the roof. The overflow of the storm water cistern above alluded to was also turned into this catch-all for the purpose of affording, as we thought, necessary flushing accommodations. Nearly two years then elapsed before we heeded a long existing conscious call to clean out this catch basin, and we confess that up to that time for some months we had felt guilty of having been grossly neglectful in not having attended to the matter earlier.

The cleansing process was then commenced in earnest, but when the labors were finished there came over us a sort of sinking feeling likened unto disgust; not because of the nauseous contents that had been removed, however, but because of the discovery of the fact that the receptacle had not needed cleaning, and that our labor had been in vain. Two more years rolled around and another attempt was made to do what seemed to be the necessary thing, but the results were identically the same as before. We were perplexed, but perplexity was soon relieved through forgetfulness, as we had not the time to look into the unexplainable conditions which had been found to exist.

Some time later as we were perusing the current copy of a well known technical journal, a short article beneath an unusual heading came before our eyes and we read it and became interested. We read several succeeding articles from time to time on the same subject before our suspicions were aroused to the fact that we had had in excellent operation for more than six years, a septic tank. The wastes that had been entering this tank were of the ordinary kind produced by a household which in this case consisted of from three to five persons. This crude appliance has now been in successful operation for twelve years and during the period has not been cleaned out to exceed five times, and then each time with the same result, namely, that the sludge found to have collected in the bottom was of such insignificant quantity as not to require removing. Without elaborating further on our experience with this much reviled receptacle of corruption and since our awakening to this exceedingly interesting subject, we have been to a greater or less degree watching the progress and development of the septic tank idea with an ever increasing interest.

Somewhat recently it became our lot to design and assist in building a city to cover ten square miles of territory, two square miles of which at the present time has largely been built upon. One of the controlling factors in our design of the land was the matter of drainage and future sewer service. Therefore, a study of the complete reticulation of the seven sewer systems in the case was gone into concurrent with the design of allotment. The future purification of the sewage as it would be controlled by the topography of the area, as a matter of course came in for a fair share of attention. We have concluded upon adopting the separate system of sewers as being the most rational one for the needs and shall therefore carry this design out as largely as consistent with the physical conditions with which we have to deal. In concluding upon this system, we had not forgotten our experience with the septic tank at our residence as hereinbefore related.

Many farm drains course more or less frequently through the territory and are temporarily available for the drainage of the many cellars that have been built and are being constructed. A demand for entrance into these and other available outlets very soon sprang up, which was granted and finally encouraged so far as these outlets had the capacity, and in following this came a stronger appeal for sewer service, which because of the greater need for improvements of much greater importance was necessarily denied, but we advised the construction of these small septic tanks where drainage was available and permitted the effluent from them temporarily to enter the drains just spoken of. These tanks, when permitted, were required to be constructed after plans made by us and under the supervision of the chief engineer.

The plan of tank adopted is circular, 3 feet in diameter and for the most part 3 feet from the under side of the outlet to the bottom of the tank. Inlets and outlets to these tanks are placed on opposite sides to each other, are made 4 inches in diameter, are placed on the same elevation and enter the tank with a downturned elbow, that the flushing in of the wastes from the soil pipe or laundry or the discharge of the effluent may not disturb the scum. The bottom of the tank is made of concrete, the walls of brick and are finished at the top of the ground the same as is an ordinary sewer manhole. The interior below the discharge pipe is washed with four coats of pure cement wash.

The capacity of the tanks are varied according to the number of people whose wastes pass into them, but for the most part contain about 160 gallons which, compared to the service reputed to be rendered by the city's tank at Champaign, Ill., would be sufficient to accommodate the wastes produced by from eight to twelve persons.

The first residential septic tank constructed in Zion City was made the size above described and served the household of twelve persons for a short time when the construction of an office building on the immediate lot required it to further serve ten more persons, but who only occupied this building during the day, and from which there came no wastes into the tank save from the lavatories and water closets. We at once feared this tank would be over-capacitated and therefore immediately set up a close watch on its action.

At the end of about six weeks after the tank had been put to use, a scum about 2 inches in thickness had formed and septic action was going on in a satisfactory way. At this writing the tank is still doing duty with a good healthy scum about 4 inches in thickness and emits scarcely any odor. The sludge has not been examined and of it we cannot speak.

Other similar tanks in the city are, under more favorable conditions, operating very satisfactorily. We have also designed and constructed two tanks of the oblong type for the use of a factory that will soon employ about a thousand hands, but owing to the limited requirements of them as yet, the tanks are not in good working order.

Taking a position which is largely based on our own experience, we have determined in the building of the city to require the universal construction of residential septic tanks, believing the effluent therefrom will be sufficiently liquefied and made incoherent by the bacterial action as to render the sewers into which it flows immune from greasy incrustations which are so much deplored by the sanitary engineer, as well as to decrease the demand for the installation of flush tanks at the upper ends of small laterals. Gradients, we believe, can also be reduced under this arrangement of things below what is now considered to be the minimum in the design and construction of the general class of sewers.

We believe in case there should ever arise a demand for further purification than what is secured by the residential septic tanks, then the cost of providing such a plant for further treating the sewage of the city at one place in one volume would be greatly minimized.

One of our most eminent English sanitarians advocates increasing the liquefaction of sewage by means of a septic tank and finishing the process by means of an anaerobic bacteria bed which he says should always be kept full of sewage. It is not probable when he advocated this scheme that he referred to tanks smaller than such as would be sufficient to care for the combined wastes of an ordinary sized town; but if this plan is an advisable one, we do not see why it may not be equally advisable to use this diminutive septic tank as the initial agent of purification through putrefaction.

In the universal adoption of this diminutive receptacle as a means of initial partial purification, it must be admitted that the costs of further purification will be very materially reduced if not in some instances wholly eliminated. Taxation for the construction and maintenance of an expensive purification plant, and for the scraping and cleaning out of the sewers, would scarcely be required or at least be materially lessened in the case at Zion City where the effluent has nearly a mile to flow in an open channel before it reaches the waters of Lake Michigan.

Of course offsetting this will be the cost of the periodical inspection of the tanks, while a triennial or quadrennial cleaning could be secured at a less cost we believe than through the means of a municipal purification plant. There is no rational means sufficiently reliable to assist us at this stage in estimating the difference in cost of such maintenance, but we feel fully justified in the course taken and hope in the future to offer something more definite as regards this scheme we have adopted and for which we have no precedent.

For designing, allocating and constructing these tanks, during the early days of our city building, the following ordinances and rules have been adopted and are strictly adhered to:

"Sec. 16 (city ordinance).—No septic tank shall be established except after plans approved by the City Engineer and countersigned by the Commissioner of Health.

"Rules Regulating the Disposition of Household Wastes.—Whenever and wherever sewers or drains from residences or other private properties are built and constructed with a view to obtaining an outlet in any other storm water drain, subsoil drain or sewer, the same shall be so constructed that its uses may be limited to the following services:

"First—No wastes from kitchen sinks, water closets, bath tubs, laundry tubs, lavatories, nor wash waters nor waste waters of any description shall be permitted to enter directly into such sewer or drain without having first been discharged into a properly constructed septic tank located in a suitable position upon the premises.

"Second—No storm waters of any description shall be permitted to enter directly or indirectly into such sewer, drain nor septic tank.

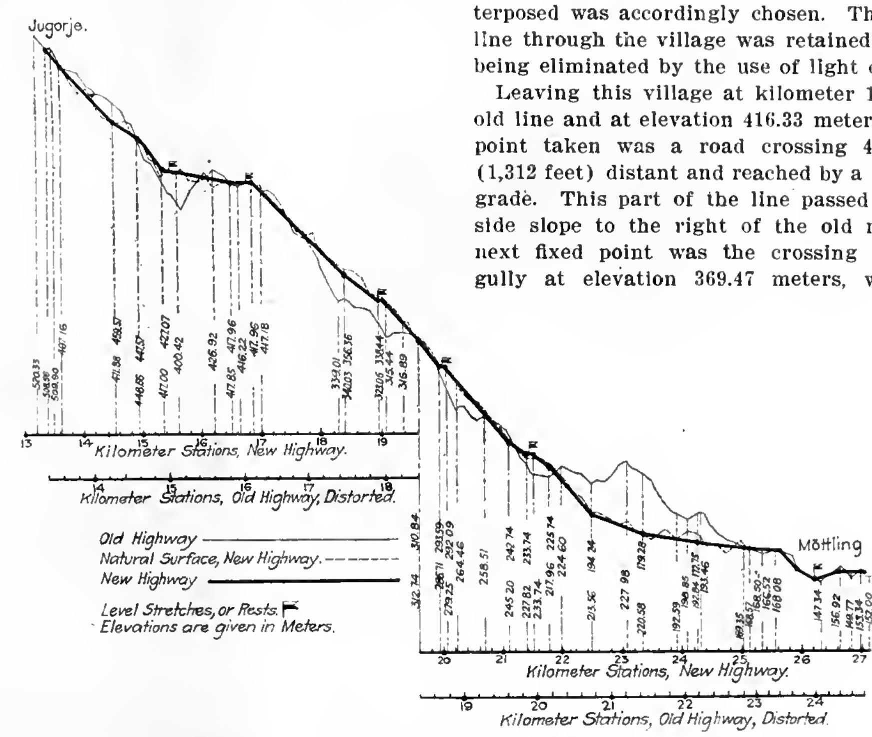
"Third—Cellar drainage will be permitted to enter such private sewer or drain providing it has no connection in any way with the interior of said cellar, and must be so constructed that no scrub waters, slops nor residential nor private wastes can possibly enter the same, nor must this drain be connected with the septic tank, but must enter the private drain at a point beyond the connection of said sewer with the septic tank.

"Fourth—The planning and building of all septic tanks are now regulated by city ordinances and under the control of city authorities."

The Coal Consumption of the Marseilles, France, street railways power plant, which contains five 1,000-kilowatt generating sets, is 2.29 pounds of dry coal per kilowatt at the switchboard.

Improvement of a Mountain Highway in Austria.

The improvement of what is known as the Karlstädter highway between Jugorje and Möttling, Austria, under the direction of Mr. Karl Grünhut, an engineer in the Imperial Austrian service, was undertaken as a continuation of a larger system of improvements carried on in the Carniola or Krain province during the preceding ten years. These improvements were largely local easings of grade. The work on this section of the Karlstädter highway called for the replacing of about 12 kilometers (about 7½ miles) of the old road, at an estimated cost of about $119,000. The total drop in elevation from the starting point to the end of the proposed improvement was 379.4 meters (1,245 feet), while the intermediate upgrades amounted to 87.2 meters (286 feet). Moreover about one-fifth of the length of the old road had grades varying from 9 to 15 per cent., making it necessary to employ extra horses in surmounting them with heavy loads. The following notes on the work have been condensed from a paper by the engineer in charge, which appeared some time ago in the "Oesterreichische Monatschrift für den Oeffentlichen Baudienst."



Profile of Highway, Jugorje to Moettling, Austria.

The old Karlstädter highway was probably first projected in 1808, but seems to have been constructed by the French for strategic reasons during their occupation of Illyria. The old alignment of the highway was first mapped out in 1832 by Lieutenant Colonel Loschan. Its profile shows such a succession of hills and valleys that it is almost impossible to obtain a clear idea of the slope of the country. Observations of the actual conditions of traffic on the road showed that the up-trips were made with a full load, the teams as a rule returning on the down grade empty. It was therefore desirable in improving the highway to make the grades as slight as possible, and incidentally to prevent the succession of up and down grades on the old roadway.

As a preliminary to the improvement, a line of benches was established on the kilometer stones along the existing highway. These levels proved the necessity of giving up the plan of simply shifting parts of the existing road, for in that case it would not be possible to do away with the vexatious counter grades. In laying out the new line two limitations added to the difficulties of the situation. The maximum grade fixed by law was 5 per cent., and official orders stated that the highway was not to enter the neighboring province of Croatia at any point along the route. Were it not for this last restriction, the new road at the upper end might have been built on a grade easily within the limit and by a much more direct route than the one finally adopted. In laying out the preliminary line grade stakes were placed every 20 meters (65.6 feet) apart.

The first 1,900 meters (6,230 feet) of the line as originally staked out for the new road was on a down grade having a total difference in elevation of 87.5 meters (287 feet), which would have resulted in a grade of 4.6 per cent. if carried straight through. However, several road crossings determined the elevations of intermediate points, so that the preliminary grades for this stretch were 4.75, 4.25, 3.00, and 5.00 per cent. respectively. To reach the next village from the last point on this stretch, it was seen that an upgrade could be avoided by making use of a cut and fill, the latter not exceeding 4 meters (13.1 feet) in height. A 1 per cent. grade with several level stretches interposed was accordingly chosen. The existing line through the village was retained, upgrades being eliminated by the use of light cuts.

Leaving this village at kilometer 16.2 of the old line and at elevation 416.33 meters, the next point taken was a road crossing 400 meters (1,312 feet) distant and reached by a 4 per cent. grade. This part of the line passed along the side slope to the right of the old road. The next fixed point was the crossing of a deep gully at elevation 369.47 meters, which was reached with a 3.4 per cent. grade. The personal interests of some of the inhabitants led to a petition asking that the proposed line over these last two stretches be changed somewhat. As the changes they proposed would have required a large loop in order to keep within the 5 per cent. grade limit, the petition could not be considered.

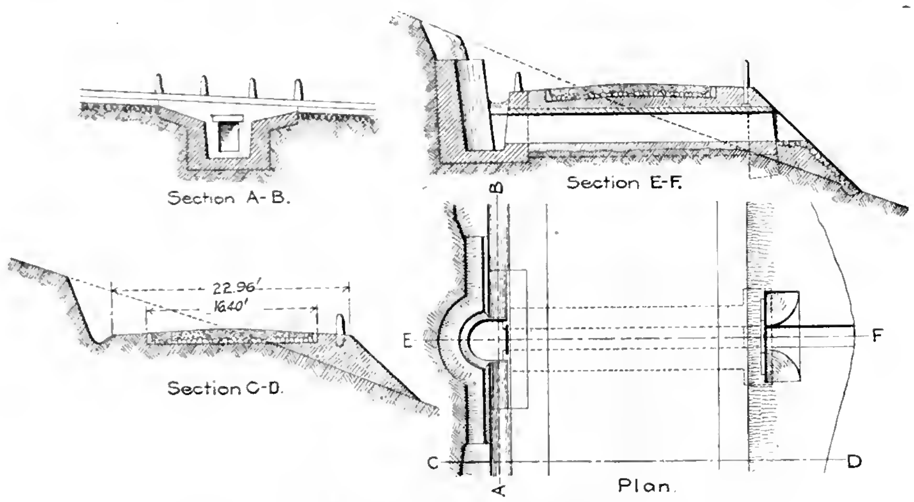
After crossing the gully previously mentioned, the line was carried 950 meters (3,116 feet) down the mountain side at a slope of 3.4 per cent. to a pass between it and a neighboring hill. A road crossing fixed the next point at elevation 312.75 meters, which was reached with a 3.6 per cent. grade. A 4 per cent. grade was used to the next village, 500 meters (1,640 feet) distant. At this point the geological formation changes from chalk to dolomite and in some places to loess. The topography also changes and instead of the succession of mounds and hollows found on the upper part of the line, from here on it follows a well defined valley with gentle side slopes.

Both slopes of this valley were considered before deciding on the final location of the line. The left slope would have given a better connection with the existing road and a shorter line, but in order to avoid introducing upgrades, such heavy masses of cut and fill would have been necessary as to have made the cost greater than that of the other line. The right slope allowed a very gradual fall toward a typical mountain stream which had to be crossed, and presented a better point of crossing it. It also permitted a much better line beyond this crossing than the left slope. Moreover, it gives a direct communication with two villages which had previously been without such communication.

From the point where the dolomite formation begins a 3.8 per cent. grade was staked out for 1,400 meters, followed by a 1.9 per cent. grade for 500 meters, and then a 3.9 per cent. grade for 950 meters brought the line to a stream crossing at elevation 193.1 meters. A variation of this last 1,400 meters (4,593 feet) of the line was considered, which would have saved 200 meters (556 feet) in length and given lighter grades, but the extra cost for cut and fill caused it to be rejected. From the last described point further determinations of grade were unnecessary, as the rest of the road into Möttling followed the comparatively easy slope of a stream.

Along the entire line as staked out, a tachymetric survey was made and enough levels taken on both sides to allow for a lateral movement of the line, and to enable cross-sections to be made for the detailed plans without further field work. About 400 levels per kilometer (about 650 per mile) were taken. The accompanying profile of the road shows heavier grades than those just described as staked out on the preliminary line. The latter provided for a minimum of earthwork without regard to length, whereas in the final location the curves were straightened as much as possible, and horizontal stretches introduced to serve as rests after long stretches of heavy grades. The profile also shows in a distorted scale of lengths the profile of the old road. The increase in the length of the new highway over that of the old was 2,200 meters (7,220 feet), the new having a total length of 13,600 meters. The total cost of the work was $106,850, or about $12,300 per mile. Places were provided alongside the road at intervals of 100 meters (328 feet) for depositing road material, to be used for repairs and maintenance.

By means of some elaborate equations and computations, it was found that the minimum cost of transportation, including the cost of the empty return trip, would be attained with a load of 937.5 kilograms (about 2,060 pounds) of useful load per horse. In making these computations, the length of road between the beginning of the improvement and the summit of the divide where the road begins to descend into the next valley, was included, in order to obtain the efficiency of the road as a whole. This total length is 16,615 meters (54,497 feet), and the elevation of the summit is 110 meters (360 feet) above the beginning of the reconstruction just described. The cost of transportation of the load of 937.5 kilograms (about 2,060 pounds) per horse for the whole distance, including the empty return, was taken as about $1.41 per ton of 2,000 pounds. The highway was found to be equivalent to a level road 2.77 times as long.



Typical Sections of Karlstaedter Highway at Culvert.

The Development of the Bituminous Macadam Pavement.

Abstract of a paper presented to the American Society of Municipal Improvements, by Fred. J. Warren.

The name bituminous macadam may be considered too nearly descriptive to be controlled by any one interest or to be a trade name but, so far as the writer is aware, it was coined for use in connection with letters patent governing methods and proportions of mixing various size mineral ingredients with bitumen, for paving purposes, and in noting the development the writer will confine himself to the experiences of Warren Brothers Company, who control these patents. The name was selected by the promoters of the pavement as descriptive of its construction, combining, as it does, the best features of the asphalt or bituminous pavement and macadam. In some respects, however, the selection of the name is an unfortunate one, as it has given the impression, in some cases, that it is a cheap pavement and, in others, that it is like macadam, which in some localities is very unpopular. Extreme cheapness is not claimed to be one of the advantages of the pavement and it is being presented to the public on its merits and not as a cheap pavement. In appearance it is not, on casual observation, materially different from asphalt, but on close examination the particles of stone which afford the more secure foothold can be seen on the surface but held firmly in place by the bituminous cement.

As explained in a paper read before the Boston Society of Civil Engineers early this year by the writer: "The principle on which the bituminous macadam pavement wearing surface is combined is the reverse of the principles on which the ordinary asphalt pavement is built. In the present asphalt or tar pavement the bituminous cement is used to support fine mineral grains, such as sand, which in themselves have no firmness to sustain traffic, in such a way that the fine mineral grains will be held or supported by the bituminous cement so that the mortar or mastic will, at all atmospheric temperatures, sustain the weight of traffic and, at the same time, resist abrasion. The bituminous macadam is built on the principle that, independent of the bituminous cement, relatively coarse and fine mineral grains should be combined in such a way as to have a firmness in themselves to sustain the weight of traffic. The bituminous cement is supported or held in place by the proper arrangement, as to size, of stone particles. The bituminous cement is used solely for the purpose of preventing attack on the stone from water and weather, and to bind the particles together sufficiently to prevent abrasion from traffic at all atmospheric temperatures and, at the same time, provide an elastic bituminous cement or cushion between the mineral particles which will deaden the jar and prevent the wearing effect caused by friction from the movement of its integral parts."

Something over two years ago, after an experience covering a period of twenty years in the refining of asphalt, manufacture of bituminous cement and the laying of asphalt pavements, the idea occurred to one of the Warren Brothers that by combining the essential principles of the most improved asphalt or bituminous and the most improved macadam pavements, a result could be reached which would: (a) Give a pavement with greater durability than asphalt. (b) Provide a foothold for horses equal to macadam and, at the same time, maintain the relative or general smoothness of an asphalt surface. (c) Overcome the necessary muddy or dusty condition of macadam and provide a pavement that, while having the density of solid stone, at the same time have great elasticity.

The theories on which the construction is based are:

First—That, with a solid, well rolled subfoundation, a thoroughly rolled base of crushed stone, such as is used in the most improved macadam pavement, is practically as good as any foundation. No one ever heard of a well laid macadam pavement failing because of the foundation.

Second—That, with a rough crushed stone base, coated with hot bituminous cement and a scientifically prepared wearing surface of bituminous concrete made of crushed stone and bituminous cement, the shifting or rolling of the ordinary asphalt pavement can be overcome. This shifting is due to two principal causes: (a) Rolling on the smooth concrete base. (b) Rolling on each other of the particles of fine sand used in the wearing surface of the ordinary asphalt pavement during hot weather when the bitumen or asphalt is in a semi-plastic and fluid condition. This tendency to shift limits the amount of bitumen which can be successfully used in an asphalt pavement to 10 per cent. or less.

Third—That by using for the mineral aggregate of the wearing surface angular particles of the hardest available crushed stone varying in size from about 2 inches to an impalpable powder in such proportion that the succeeding sizes will fill the coarser voids in the larger sizes, a far greater density could be secured than had previously been attained in either macadam or asphalt pavement construction. To secure the best results it is essential that the crushed stone after heating be separated into several sizes and then mixed by machinery in definite proportions by weight.

Fourth—That, by increasing the density and thus decreasing the voids and, by having the bulk of the mineral aggregate composed of coarse angular particles of stone, the voids can be thoroughly filled with bituminous cement and, by using a bituminous cement which is unaffected by water, a thoroughly waterproof wearing surface of bituminous concrete can be produced.

Fifth—That particles of carefully selected, crushed hard stone, held firmly in place by an elastic bituminous waterproof cement, would provide for the wearing surface of a pavement, one of the most durable substances known and a sufficiently rough surface to give an ideal foothold for horses.

In inverse ratio, the percentage of voids in the mixture of different sizes of stone used indicates its density or specific gravity. Uniform size particles of any shape or size contain approximately 40 per cent. of voids. Ordinary sand contains from 30 per cent. to 38 per cent. of voids; very seldom as low as 30 per cent. The most carefully prepared mixture of several grades of sand used in the most modern asphalt pavement mixture contains 25 per cent. of voids. The using of graded stone reduces the voids in the mineral mixture and the rigidness of the stone permits of the use of a softer bituminous cement than can be used with sand.

It is owing to minimizing the exposure of the bitumen and the use of a softer bituminous cement which would require more exposure to render it inefficient that it is believed the cement itself will retain its binding or cementing properties longer than would be possible in sand mixtures.

By using crushed stone varying in size from a maximum of two inches to an impalpable powder in exact proportions, as above described, we are able to reduce the voids to 10 per cent. and, by using enough of the bitumen to thoroughly coat all the particles and fill all the voids, can get a thoroughly waterproof wearing surface. We do not mean by this that it is advisable to wet the pavement excessively. Any paving material will wear longer if dry than wet. Continual moisture and mud on a pavement, combined with the abrasion of steel wagon tires, produces the condition which is employed to saw and plane stone and other hard substances. The bituminous macadam does not entirely overcome this, but by filling the voids with an elastic bituminous cement, which is absolutely unaffected by water, it does reduce the effect to a minimum. Like other forms of pavement, bituminous macadam is in better condition for horse and foot traffic when dry and clean than when wet and dirty. It should, therefore, be frequently cleaned the same as other forms of pavement.

The bituminous macadam surface is so dense and the particles of stone so firmly held in place by the bituminous cement that, even when made of the hardest trap rock, a section of the pavement when chilled and broken will fracture through the stone. In other words, the stone will break before it will cleave from the cement.

With the assistance of an able chemist of large experience in the study and practical use of bitumens and bituminous construction and, by devising considerable entirely new apparatus found necessary, the first nine months of the history of this pavement were devoted to diligent laboratory work to determine the best ingredients and the best combination of them to carry out the theory of the proposed construction. This brought us to the Spring of 1901, when the prospects of success seemed sufficiently sure to warrant the seven Warren Brothers (all of whom had devoted their business lives and training in the several branches of the bituminous and asphalt paving business) in dropping their other interests and assisting in the development. During the first year we succeeded in getting small contracts aggregating something less than 25,000 square yards in seven cities of the United States, five of which are within fifty miles of Boston. Laid with inadequate equipment and crude ideas of detail some of this work, while generally satisfactory, does not fairly represent the possibilities of construction.

The attention attracted by the samples laid in 1901 was far beyond the expectations of anyone and early this year it was realized that much trouble would be encountered in executing work contemplated, and orders were placed in January for seventeen plants of an entirely improved pattern and with a capacity of 1,500 yards a day each. These plants were all of a modern type of rotary drums, elevators, elevated screens and bins which would separate the stone into six different sizes and scales which would weigh each separate size of stone. The work of getting the plants out of the shop as fast as desired was an impossible undertaking and the wet weather of early Spring and Summer made it impossible to have work well under way until after August 1. It became evident early in the present year that, to cope with the demand, a large increase in capital, equipment and practical working force was essential. The result has been that the work constructed and contracted for during the present year amounts to 620,900 square yards in 39 cities.

In one respect the development has been a disappointment to its promoters and that is in the matter of cost of construction which proves to be as great as, and in some localities greater than, that of asphalt. This does not warrant the taking of more contracts at the prices of some of the earlier contracts taken. The bituminous cement and stone in the bituminous macadam base cost practically the same as the hydraulic cement and stone in the hydraulic concrete foundation of the asphalt pavement, so that the only saving in cost of foundation is the sand and part of the labor employed in mixing concrete. The crushed stone used in the wearing surface generally costs twice and sometimes three times as much as the sand used in asphalt pavement construction. The bituminous and stone mixture used in the wearing surface of the bituminous macadam is so much more dense and tough than the sand mixture of the asphalt pavement that the time, labor and power required to properly mix the ingredients and handle the mixture on the street is, with bituminous macadam, fully double that of asphalt. This is a condition which we did not foresee. Like all forms of construction the cost varies, very much depending upon the local cost of labor and materials, size of contract and other local conditions.

One important thing which has been developed to a certainty is that bituminous macadam can be laid with special design to provide a rough surface so as to afford a good foothold for horses on very steep grades. In the city of Pawtucket, R. I., the pavement has been in successful use since May, 1901, on a street with a grade of 12 per cent. and has received the unanimous endorsement of engineers and practical road builders who have critically examined it. The Massachusetts Highway Association devoted its quarterly meeting held in May last to the examination and consideration of this pavement. I take the liberty of quoting from the remarks of Mr. J. E. McClintock, of the Massachusetts Highway Commission, made at that meeting: "It has unquestionably solved the problem of pavement for steep grades and, if its cost were double what is asked for it, it would be the most economical pavement for such conditions."

Several Sewer Stoppages occurred during 1901 in Jacksonville, Fla., according to the annual report of Superintendent R. N. Ellis, caused by defective work by plumbers in making house connections. In the worst case the sewer was choked with sand for over 100 feet. The sewer was about 10 feet deep at that point, and the ground was thoroughly saturated with water.

The Proportions of Centrifugal Fans.

An interesting account of a method for determining the proportions of fans for setting up the movement of air against low pressures is given in a recent paper on mechanical draft read by Mr. F. R. Still, of Detroit, Mich., before the Western Engineers' Club and printed in that society's "Journal." Except for a detailed comparison that is made between the chimney and this type of fan as related to mechanical draft, the paper is practically treated in full in the following abstract.

The author describes briefly the forces at work in the discharge from a blower, and to facilitate his explanation refers to three diagrams which are combined in the one reproduced herewith. For his purposes in the definition of these forces, he starts with the dynamic pressure and the static pressure, the one of which always works against the other, with the result of practically producing a third pressure, which pressure he names air velocity pressure. His analysis of the fan action is as follows: the pressure and movement of the air is due entirely to the centrifugal force produced by the air sliding off the fan blades. The centrifugal force is in direct ratio to the square of the number of revolutions. With a fan wheel of given proportions the centrifugal force holds a direct ratio to the peripheral velocity. For comparison he creates a fourth pressure, a peripheral velocity pressure, based on an assumption that if the air were moving at the same velocity as the fan tips, a pressure

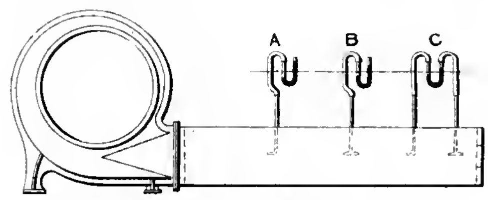


Diagram of Fan Discharge Pressure.

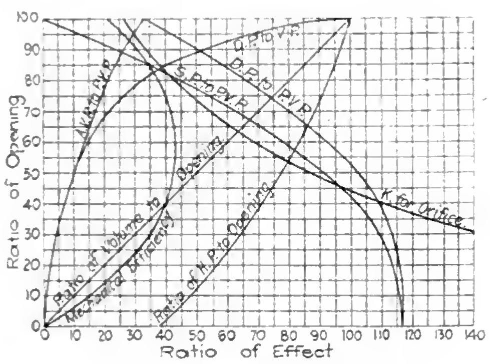
equivalent to the peripheral velocity pressure would be produced.

An accompanying diagram shows a blower discharging into a pipe 6 or 8 feet long with U-tubes or water gauges for measuring the pressure. A is the dynamic pressure tube and B, the static, the former attached to a bent pipe that faces the air current and the latter to a pipe which is at right angles to it. Concerning the behavior of the water gauges, the author explains that if the end of the discharge pipe is open there will be no difference in the level of the water in the two legs of B, as there is no resistance to the air current and therefore no static head. That in this case, A gives the combined reading of dynamic pressure and velocity pressure. That if a diaphragm is inserted in the end of the discharge pipe, reducing the outlet area, say 50 per cent., the water in A rises higher than in the previous case and the reading of B is almost the same as it was in A. That by ascertaining the difference between the present readings of A and B, or rigging up a tube as shown at C, the velocity pressure is obtained. That from this pressure can be determined the quantity of air passing through the pipe. That if the discharge pipe is entirely closed, the water rises higher in both A and B than before and both are alike. The author thought these points were not fully understood by many engineers and believed it explained the large capacities sometimes ascribed to blowers, owing to the assumption that a Pitot tube, designated by the author as the dynamic tube, gave the pressure due to the velocity of the air.

With regard to the relative capacities of fans under different conditions of service, the author presented the accompanying chart of curves, these applying to steel-plate fans, although the difference, he says, is not very great for any type of centrifugal fan. His discussion of the curves is as follows:

"The length of the fan blades and the speed have more effect than anything else. The longer the fan blades, the greater the centrifugal force at a given speed. Again, the greater the peripheral velocity up to about 6,600 feet per minute, the higher is the mechanical efficiency. Above 6,600 feet it begins to fall off very rapidly, much the way it does when the outlet is entirely closed. The ratio of opening at the left might be taken as the ratio of resistance. It is the percentage of opening in the discharge as compared with the total discharge area. The ratio of effect is the relative effect produced on the different elements of the fan by restricting the discharge.

"Supposing we have a fan with an unrestricted inlet and outlet that will deliver 25,000 cubic feet of air per minute at a head of 0.33 inch, with a given peripheral velocity, requiring 6.16 horse power. If we close the discharge outlet to 50 per cent. of the full area it will deliver only 12,500 cubic feet. The pressure will be increased to 1.03 inches, and the power to drive will drop to 4.8 horse-power. If we still further reduce the outlet to 20 per cent. of the full area, the capacity will drop to 5,000 cubic feet. The pressure will increase to 1.15



CURVES FOR STEEL PLATE FANS.

inches, and the power will be decreased to 3.45 horse-power.

"To determine exactly how a fan will perform is almost impossible, as all the conditions incident to its installation can never be foreseen. But we can get very close to it, as a rule. It is customary, when little is known about the plant the fan is going into, to assume that the resistance is equivalent to restricting the discharge outlet 25 per cent. This has always proved sufficient in the average mechanical draft plants we have put in. Some very large plants, with very large economizers, long smoke flues and other obstructions, have to be treated differently, the friction being figured up and added to the velocity head to determine the dynamic pressure."

For purposes of illustration the author assumed the case of a 1,000-horse-power boiler plant involving a consumption of 3,253 pounds of coal per hour. Allowing 18 pounds of air per pound of coal, 5 per cent. for ash and 5 per cent. for leaks, the author calculates that the fan will have to handle about 65,000 pounds of gases per hour at 500 degrees, or 27,250 cubic feet per minute. Continuing, he says: "We want a draft of 1 inch at the inlet, and having allowed for leaks in the above capacity, we can expect the same at the bridge wall. By adapting Murgue's formula for equivalent orifice, $A = KQ \div \sqrt{P}$ to obtain the inlet area, we find on the chart that $K = 0.485$; A is the area in square feet; Q is the quantity in thousands cubic feet; P is pressure in inches. Thus $A = 0.485 \times 27.25 \div \sqrt{1} = 13.2$ (square feet; that is, 49¼ inches in diameter). The area of the inlet should not exceed 40 per cent. of the area of the side of the wheel. Thus $13.2 \div 0.40 = 33$ (square feet, or 66 inches equal to 5 feet 6 inches, diameter).

"The velocity due to 1 inch pressure at 500 degrees is $81.5\sqrt{1} = 81.5$ feet per second, or 4,890 feet per minute. Referring to the chart, we find the ratio of dynamic pressure to peripheral velocity pressure is 0.73." The author then figures that the velocity of the fan wheel will be $8.15 \sqrt{1.37} = 95.5$ (feet per second) $= 5{,}730$ feet per minute, 1.37 being the reciprocal of 0.73, or the peripheral velocity pressure. The air velocity is thus about 85 per cent. of the peripheral velocity.

To find the blast area of the fan wheel he proceeds as follows: $27{,}250 \div 5{,}730 = 4.76$ (square feet). Multiplying by 3, an arbitrary constant established by experiment, an area of $4.76 \times 144 \times 3 = 2{,}055$ square inches is obtained. With a free discharge the author says the constant is 2.2 on fans of this type. The diameter of the wheel being 66 inches, the width at the periphery in inches is $2{,}055 \div 66 = 31.2$ inches.

From this point the author says different makers have ideas of their own, founded on no particular reasons as regards total width of fan. The only reason for beveling the side of the fan blades, as is the universal practice, is, he believes, to give strength and stiffness to the wheel with light material, the side plates forming a circular cone and acting as a truss between each blade, much stronger than if the side plates were flat. The correct principle, he asserts, is to make the circumference at the inlet multiplied by the breadth equal to the circumference at the periphery multiplied by the breadth at that point. To facilitate manufacture and do away with special patterns, the bevel is made 20 degrees, the tangent of which is 0.3639. The length of the blades is made 8⅜ inches and the overall width at inlet will be 37¼ inches. The width of the housing is taken 38 inches. As the inlet has 1,900 square inches area, the outlet will be $1{,}900 \div 38 = 50$ inches, that is, 38 inches wide by 50 inches high.

The speed of the fan will be $5{,}730 \div (5.5 \times 3.1416) = 332$ revolutions per minute. The power required to drive will be $(27{,}250 \times 5.2) \div (33{,}000 \times 0.40) = 10.75$ brake horse-power. The factor 5.2 is the number of pounds draft per square foot, equivalent to 1 inch water gauge, and the factor 0.40, the efficiency of the fan. If the fan engine required 50 pounds of steam per horse-power per hour, it would amount to 538 pounds of steam or 1⅝ per cent. of the evaporating capacity of the boilers. With this fan the author believes it would be advisable to put on a stack 5 feet in diameter, so as to reduce the resistance as much as possible. He stated in the discussion that if a chimney is high enough to produce, say an air velocity of about 1,200 feet, whereas a fan at a given speed would produce only 1,100 feet, then the chimney would help the fan; but that if the case was reversed, and the chimney produced only 1,100 feet velocity, the higher the chimney, the greater is the load on the fan. That is, there is a friction that would have to be overcome. He explained, for example, that if a 130-foot stack failed to produce sufficient draft for a case in hand, if a fan were used, the chimney was an obstruction and it would be better to cut off the stack from the fan.

Fire Test of a Lock-Woven Metal Concrete Floor.

Early this year a fire test was made by Mr. W. W. Ewing, at that time engineer of tests of the Bureau of Buildings of Manhattan, New York, on a "lock-woven metal concrete" floor built under the designs of W. N. Wight & Company. The object of the test is stated as follows in Mr. Ewing's report: "To record the effect of the continuous heat of a wood fire below the floor system, averaging not less than 1,700 degrees Fahr. for not less than 4 hours, the filling between the two beams being loaded with a distributed weight of 150 pounds per square foot of its area and all carried by such filling; the fire being extinguished at the end of the test with a stream of water directed against the bottom of the platform and discharged through a 1⅛-inch nozzle under 60 pounds pressure for 5 minutes, flooding the top of the platform with water under low pressure and then again applying the stream of water through the nozzle under the 60 pounds pressure to the bottom of the platform for 5 minutes." After this test the floor was loaded to 600 pounds per square inch and then unloaded gradually.

The test was made at a special brick house built for the purpose on the East River front. It measured 14x14 feet inside, and was 10 feet high. Two and a quarter feet above the ground there was a grate covering the entire area, with openings through the walls below it, while above it there was a door in one wall with a window directly opposite. The roof was the floor arch to be tested. Four 10-inch 35-pound steel beams, 5 feet apart on centers and well tied together, formed the framing for the roof. The latter is designed in accordance with a principle stated as follows in the report: "When galvanized steel wires, meshed in continuous sheets, are incorporated in the lower section of a high-grade Portland cement cinder concrete flat arch construction as a reinforcing element, spanning the distance between the upper flanges of standard I beams, the beams being haunched and protected with similar concrete, the effect of the combination is to afford a suitable means of fire protection for the beams and space above, and also for carrying the ordinary loads met with in common practice while subjected to serious fire and water test."

The roof was laid on a temporary center. The lower 5 inches of the concrete was mixed in the proportion of one part of Saylor's Portland cement, two parts sand and five parts steam ashes, and the lock-woven fabric was imbedded in it. The top of this course was 1¾ inches above the tops of the beams, which were protected on their bottom flanges as shown in the diagram. The fabric was made of No. 9 wires running across the beams every four inches and No. 10 wires running parallel with the beams and spaced 6 inches center to center. The wires were knotted together by the patented process controlled by the company. This course of concrete was laid on January 7 and 8. On January 25 it was covered with 3 inches of concrete filling, made of one part Victor Portland cement, two parts of sand and ten parts of steam ashes. The centers were removed the day before this top finish was laid, and it was then found that the protection of the lower flanges of the beams was not complete. The defective places were accordingly filled with a mortar of equal parts of Portland cement and sand. The ceiling of the center bay was plastered on January 30 and 31 with half an inch of King's No. 1 browning mortar.

On January 8 the temperature was 31 to 33 degrees. During the entire period of construction of the lower or principal course of concrete, the weather was stormy, and light snow, sleet or rain fell during the whole time of laying the concrete. A low coke fire was maintained in the building during the period of setting of the arch, and after the plaster had been put on, thereby facilitating the setting and drying of the materials.

The fire test was begun at noon, February 4, when the temperature was 16 degrees. The roof was loaded to 150 pounds per square foot, with brick. Pine and mixed cord wood was used for fuel, and the flames were accelerated at the start with kerosene. The temperature inside the house was measured by a LeChatelier pyrometer; at 2 p. m. it was 1,688 degrees Fahrenheit; 2:30, 1,967; 3:00, 1,553; 3:30, 1,877; 4:00, 1,733; 4:30, 1,688; 5:00, 1,796; 5:15, 1,472. At 5:18 a stream of water was thrown on the ceiling from a hose connected to a fire-boat, and this stream was continued for 5 minutes. Water was then flooded over the top of the roof for 6 minutes, and finally a stream was again played on the ceiling. On February 5 the roof was unloaded. The level readings showed that the defections at the center of the north and south beams and the arch between them were as follows:

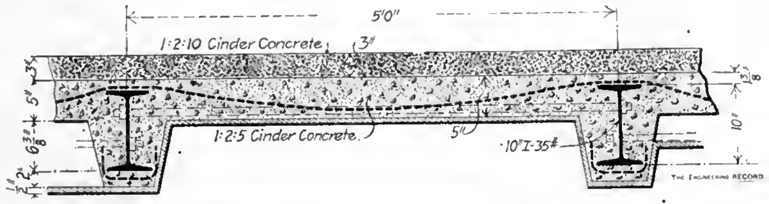
Time.	N. Beam.	Arch.	S. Beam.
12.48	0.02	0.01	0.005
2.37	0.39	0.19	0.14
3.45	0.42	0.11	0.11
4.30	0.66	0.43	0.78
After cooling	0.195	0.435	0.11
After cooling and unloading	0.13	0.425	0.09

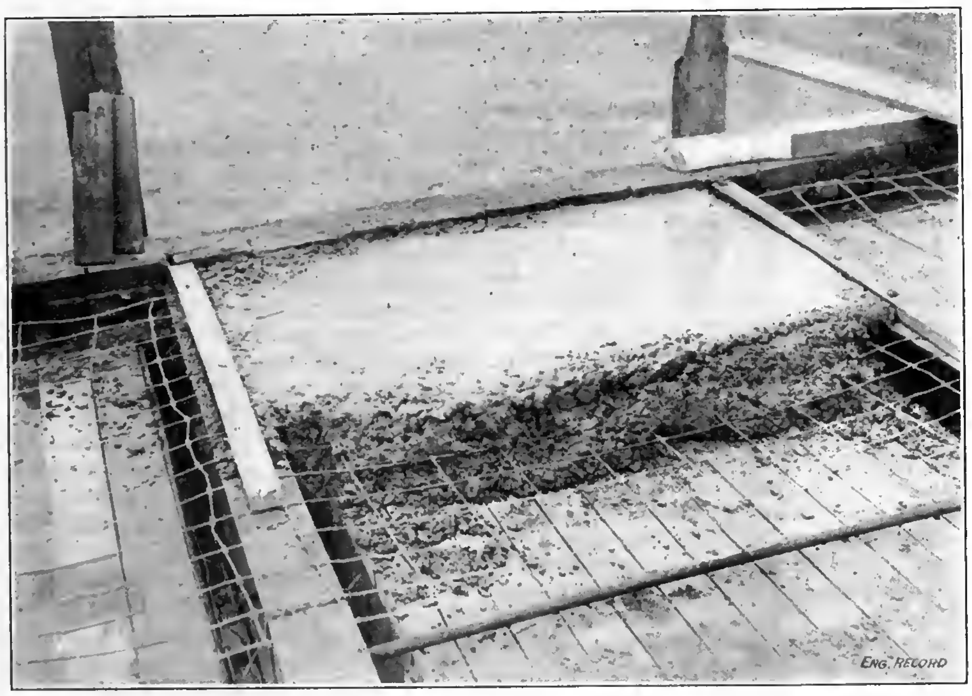
The examination of the arches was made on February 6, and the results are stated as follows in the report: "The plaster applied to the ceiling was practically all destroyed by the fire and water. The metal ceiling of the south bay was also destroyed. The tie-rods of the south bay were found in good condition. The tie-rod in the north bay, east of the center, showed a slight distortion. The tie-rod east of the center in the principal arch was exposed almost its entire length. About seven meshes of the metal fabric were exposed next the latter tie-rod; otherwise, the center and north and south arches were found in good condition. The beam protection, except in a few places where the cinder concrete had not been placed, was found in good condition."

The heavy loading test was begun on February 7, but as sufficient brick for the purpose could not be obtained on that date the full weight was not placed on the arch until about noon on February 8. This load remained in place 48 hours, and was then removed. The log of the test is substantially as follows, the deflections being at the center points of the beams and arch, and the loads in pounds per square foot.

Feb.	Hour	Load lbs.	Deflection, inches N. Beam.	Arch.	S. Beam.
7	10.30 a. m.	None.	0.000	0.000	0.000
7	12.15 p. m.	150	0.045	0.004	0.055
7	3.00 p. m.	300	0.095	0.035	0.120
7	4.30 p. m.	300	0.125	0.055	0.140
8	8.30 a. m.	300	0.127	0.067	0.131
8	11.00 a. m.	450	0.154	0.070	0.145
8	1.00 p. m.	600	0.195	0.115	0.190
10	1.00 p. m.	600	0.195	0.120	0.197
10	2.30 p. m.	450	0.165	0.107	0.180
10	3.30 p. m.	300	0.141	0.092	0.128
10	4.25 p. m.	150	0.082	0.070	0.070
10	5.04 p. m.	None.	0.034	0.035	0.011

The final opinion of Mr. Ewing on all these experiments is as follows: "The concrete forming the floor was but slightly damaged by the test. The beam protection was effective. The beams suffered no material permanent set. No fire or water passed through the floor arches, and they carried the loads safely as provided by law."





The Flooring System Forming the Roof of the Test Building.

The Placing of Water Meters and a system of close inspection in Grand Rapids, Mich., resulted in a decrease in the amount of water pumped of 200,000 gallons per day over that of the previous year, according to the latest report of the Board of Public Works. For the year ending April 30, 1902, the number of scheduled services was 8,818, and the number of metered services, 2,248. The number of house inspections made during the year was 8,437, and 1,331 leaks were found. Five inspectors were employed, two reading meters.

Book Notes.

No one acquainted with the manufacture and erection of steelwork in buildings can fail to deplore the waste of money which is often caused by designers of such material in their endeavor to pare down sections to a minimum. The large proportion of the total cost due to unnecessary expense in the shop and field is sometimes astonishing. With the best intention in the world to save any waste of a client's money, the failure to understand shop and erection requirements leads to designs theoretically economical but practically expensive. Steelwork detailing ought to be very largely routine work, following standard designs wherever possible and conforming to reasonable shop rules. Consequently great credit is due the Engineering Department of the American Bridge Company for a volume of "Standards for Structural Details" it has recently compiled. It is a collection of tables, detail drawings and rules for draftsmen embodying the results of many years' experience and adopted for all shops of the company. With its assistance any architectural draftsman with sufficient knowledge of steelwork to be placed in charge of such design should be able to turn in good plans from the manufacturer's as well as architect's point of view. At the present time, when an architect's steelwork plans are received at a shop, they have to be entirely redrawn and redetailed so as to make construction possible. A large part of this work would be saved were the original drawings properly prepared in the first instance, and this good result will follow the intelligent use of the book in question. The publication of the book has been very largely a free contribution by the company to the literature of good architectural engineering, and Messrs. Schneider and Wolfel have placed the profession under a considerable obligation by carrying the task through to such an excellent completion. The book is for free distribution to parties who can show reason for receiving it.

Mr. Hugo Feldmann, head instructor at the Nienburg industrial school, has collected 525 sketches of chimney tops which are published at $1 by the Helwingsche Verlagsbuchhandlung at Hanover. The sketches are well executed and printed, and many seem admirable, but there are a few which were not designed with proper regard to draft and a few which apparently record the nightmare visions following a prolonged affenbummeln. But it is hard to bring together 525 chimney pots all pleasing to every one's taste, and with such an extensive field for a choice the work ought to prove useful to all designers.

A book which ought to interest a large circle of American readers who have country estates is Prof. Vittorio Niccoli's "Costruzione ed Economia dei Fabbricati Rurali." The author is one of the faculty in the Royal Agricultural School at Milan, which is taking an important place in the rehabilitation of Italian agriculture. The book explains the principle which should govern the location and construction of farm buildings, their drainage, and the details of various sheds, vaults and other structures employed in making wine, extracting olive oil and storing the products of the farm. The work in Italy is all of a permanent character which would meet with little favor in the United States, yet it is none the less interesting. The book is published at 70 cents by Ulrico Hoepli, Milan, in his well-known series of manuals. The "Magnetismo e Elettricità" of Prof. Francesco Grassi, in the same series, has just reached a third edition. It is a book of over 600 pages of fine type, well printed and profusely illustrated, and is sold at $1.10. It is an elementary work, but has been revised so close to date that the electrical plant of the Manhattan Railway in New York, and the various wireless telegraph systems, are briefly explained.

One of the best collections of hydraulic diagrams issued for some time is an atlas of eleven plates measuring 8x5 inches and showing the relation, according to the Kutter formula, of the slope of a conduit or channel, its hydraulic radius and the mean velocity of uniform motion within it. A diagram is given for each of the following coefficients of roughness: 0.009, 0.010, 0.011, 0.012, 0.013, 0.015, 0.017, 0.020, 0.025, 0.030, 0.035. Both the horizontal and vertical scales have logarithmic divisions, the abscissas being slopes and the ordinates velocities. The curves, which are very nearly straight lines, are for hydraulic radii of 0.1 to 25 feet, and show very clearly the peculiarities of the formula. Owing to the uncertainty usually attending the choice of a proper coefficient of roughness, it is fruitless to observe great accuracy in employing the Kutter formula, and these diagrams will serve most purposes. Their accuracy is assured by the fact that they were prepared by Prof. Irving P. Church. They are published by John Wiley & Sons, New York.

Few books bear the mark of more painstaking revision and improvement in succeeding issues than the "Text-Book on Roofs and Bridges" of Professors Merriman and Jacoby. Part III. of this work, on bridge design, has just been revised for the fourth time, and its new form, while somewhat smaller than that of the first edition published eight years ago, is a marked advance over it. The changes in bridge design in eight years have been very great. Wrought iron has given place to steel, live loads have increased surprisingly, rolling mills are furnishing a large variety of shapes, and machine tools have been made larger and more efficient, while, on the other hand, standardization has been making great changes in detailing, and technical education is supplying a better grade of assistants for the designing office. The effect of these influences has been such an alteration in bridge design that the authors of this work have entirely rewritten it, although preserving the general plan of the treatment. Examples of details no longer good practice have been superseded by others showing current designs, so that a large part of the illustrations are also new. A particularly good feature is a list of references to the leading articles on bridge design in the technical press. The book is one of which the authors—and the engineering profession—may be justly proud. It is published at $2.50 by John Wiley & Sons, New York.

No matter how good may be the design of a machine, its value is diminished if the material of each part is not chosen for its particular service. This fact is so evident that the absence of a concise handbook on the selection of materials for machinery has been noticeable. Prof. Albert W. Smith has at last filled this need by a small volume entitled "Materials of Machines," published at $1 by John Wiley & Sons, New York. Its clearness of statement is noteworthy, and its value as a reference book is high.

What becomes of all the surveying instruments has been a favorite engineering conundrum, for they are turned out in a steady flood every year which should apparently glut the market very soon. Just the same thing is true of books on surveying, particularly in Germany; in the United States there is more moderation in production, and the appearance of a new work is a pretty fair indication that some one has found a new treatment of old subjects sufficiently useful to warrant a publisher to produce it. Accordingly the "Plane Surveying" of Prof. Paul C. Nugent, published at $3.50 by John Wiley & Sons, New York, has been examined with more than usual interest to see what news the author had about such an old story. Briefly stated, the novelties must be sought in the careful presentation of the subject from a teacher's point of view, in which respect some of the sections are particularly well developed. Strangely enough the most striking feature is the discussion of the well-threshed subject of instrument adjustments; the novelty lies in the introduction of the methods of descriptive geometry in explaining the operations.

Among the volumes issued in connection with the bicentennial anniversary of Yale University was a large octavo by Prof. A. Jay Dubois on "Kinematics, Statics, Kinetics, Statics of Rigid Bodies and of Elastic Solids," forming the first part of a series dealing with the applications of mechanics to engineering problems. In a very general way the book may be said to be an amplification of the author's three-volume "Elementary Principles of Mechanics," but many of the discussions are more direct and the applications are varied and useful, particularly those involving the principle of least work. The book is sold at $7.50. Another volume of the series is a twelfth edition of the author's "Stresses in Framed Structures." The general form and arrangement of the earlier editions are preserved, but a number of improvements in some sections have been made. It is to be hoped that some of the antiquated details and examples of work will be replaced by more modern types, affording equally good instruction to students, in the next edition. The book is sold at $10.

The "Proceedings" of the third annual convention of the American Railway Engineering and Maintenance-of-Way Association have appeared in a well-printed pamphlet of 500 pages. This association was formed to supply a much-needed organization for the civil engineers engaged in railway work. The details of railway engineering are so special that their discussion by the general engineering societies has not been a success; and the system of committee investigations, which has proved so useful in collecting and collating information on single topics, can be best carried on in specialized societies. The "Proceedings" of the association above named demonstrate fully the importance of its opportunities for doing good, particularly in standardizing structural work, a service which the associations of master mechanics and car builders have already performed in their branches.

It has doubtless drifted in upon the horizon of many of the readers of this journal that there has been a tremendous recent change in the ideas of up-to-date mathematicians concerning elementary geometry. Until lately we have basked in the light of demonstrations scintillating coldly down the halls of time from the age of Alexandria's splendor. In our boyhood, Euclid was a name revered, but, sad to say, there are few mathematicians who now fear to shy a stone at his work. They say he is illogical, that his axioms are as reliable as tips on the stock market, and his work fairly creditable for old Egypt, but not up in the van of modern progress. So, Lindemann, Hermite, Dehn and many others have built up a new geometry, beautifully logical when understood, but so very, very hard to understand. The great work on the subject, by Lindemann, has not appeared yet in English, although it is understood that the authorized translation by Dr. J. Brace Chittenden has been practically finished. That is a monumental treatise, however, and for readers who desire a shorter outline the Open Court Publishing Co., Chicago, has brought out at $1 a translation by Dr. Townsend of the scholarly address on "The Foundations of Geometry," delivered by Prof. David Hilbert at the unveiling of the Gauss-Weber monument at Göttingen three years ago. The book is one of the most important recent short contributions to mathematical literature.

A fourth edition of Prof. R. C. Carpenter's "Heating and Ventilating Buildings," has been issued by Messrs. John Wiley & Sons, New York. The matter has been considerably revised, and, besides three new chapters, includes much additional information. This relates to the determination of carbonic acid gas, the anemometer and its calibration, the theory of the flow of air through orifices, pipes and by the force of the heated column, the transmission of heat through building materials, superheated steam in radiators, tests of blower systems, the condensation in radiators, house heating boilers, a summary of approved methods for the design of steam and hot water systems of heating, various patented systems of heating and the arrangement and proportions of furnaces for hot air heating. The new chapters are devoted to the fan or blower for moving air, to mechanical systems of heating and ventilation and to school house heating and ventilation. A number of tables have been added and the index has been improved. The book has 562 pages, an increase of over one-third over the former volume, and sells for $4.

A publication entitled "American Art in Bronze and Iron," edited by Mr. William Donald Mitchell, has been undertaken by John Williams Bronze Foundry, 556 West 27th Street, New York. Its purpose is to illustrate the best designs of architects, decorators and sculptors as exemplified by the company's work, which is too well known for variety and quality to need comment here. The initial number is devoted to memorial tablets, and it contains a large number of excellent engravings of examples by eminent designers. Succeeding issues will illustrate bronze entrance doors and grilles, bank counter screens, lamp standards and lanterns, sculpture in bronze, and miscellaneous metalwork of architectural, decorative and ecclesiastical character. The value of such a publication is evident to all architects, and the fact that it is for reasonable free distribution places it within the reach of all.

Another publication for free distribution is a pocket edition of lists of spirit levels and bench marks along the New York State canals. It has about 90 pages and a large folding map, and is reprinted from the 1901 report of Mr. Edward A. Bond, State engineer and surveyor. The manner of running the levels is fully explained and there is a historical sketch of other important leveling in the same district.

It is France which has been setting the pace of late in new methods of travel, and that land is as far ahead of others in the new art of dirigible ballooning as in automobile running. It is not strange, therefore, that Ch. Béranger, 15 Rue des Saints-Pères, has published a 350-page work, "Les Dirigeables," by M. H. André, a member of the Société des Ingénieurs Civils, for the interest in the subject has already led to the appearance of several healthy journals devoted to aeronautics and numerous monographs and less ambitious books. The new book is in three parts, the first on the design and construction of balloons, the second on means of propulsion, and the third on the historical aspect of the subject, from the project of Meusnier in 1783 to the experiments of

Zeppelin and Santos-Dumont. The book seems to be a serious study of a subject which few people consider very seriously in the United States. It is published at $2.50.

Meeting of the American Society of Municipal Improvements.

The ninth annual convention of the American Society of Municipal Improvements was opened in the Chamber of Commerce, Rochester, N. Y., Tuesday afternoon, with addresses of welcome by Mayor A. J. Rodenbeck, and Secretary John M. Ives, of the Chamber of Commerce. The response was by the Society's second vice-president, Mr. G. M. Ballard, of Newark, N. J. Under the regular order of business, which was then proceeded with, the following applicants were elected to membership in the association: John Rowson and Edgar S. Kiefer, members Board of Public Works, Grand Rapids, Mich.; J. B. Nelson, city engineer and Edwin D. Logsden, member, Board of Public Works, Indianapolis, Ind.; Augustus P. Eggers, commissioner and J. Crowell Mundy, superintendent, Board of Public Works, Newark, N. J.; Leon D. Conkling, city engineer, Elmira, N. Y.; G. A. Parker, superintendent Kenney Park, Hartford, Conn.; Edward J. Johnson, city engineer, Nashua, N. H.; William S. Crandall, editor "Municipal Journal and Engineer," New York city; William N. Radenhurst, assistant engineer of water-works, John F. Skinner, assistant engineer of water-works, William J. Stewart, first assistant city engineer, Joseph E. Putnam, consulting electrical engineer, J. Y. McClintock, commissioner, and Thomas Nevill, deputy commissioner, Board of Public Works, Rochester, N. Y.; Frederick A. Snyder, city engineer, Williamsport, Pa.; Clarence D. Pollock, assistant engineer, Bureau of Highways, Brooklyn, N. Y.; William Pierson Judson, deputy State surveyor, Oswego, N. Y.; F. H. Woods, chairman, and J. Crane, member, Board of Control, Toronto, Canada; N. J. Kerr, city engineer, Ottawa, Canada; John R. Barlow, city engineer, Montreal, Canada, and L. Y. Cochran, Supt. of Highways, Allegheny, Pa.

In his annual address, President Edwin A. Fisher spoke of the need of organized effort on the part of municipal officials in order to bring about better and more economical methods of construction and maintenance in municipal works. It was to be regretted that a large number of such officials did not recognize the work this society was undertaking and unite with it in its efforts to promote the public good. The work of the society was, he said, grouped into eleven sub-divisions under the following heads: street paving electric street lighting, sewerage and sanitation, disposition of garbage and street cleaning, water works and water supply, municipal data, park development and maintenance, taxation and assessment, city government and legislation, and municipal franchise and review. Inasmuch as there were other associations devoting attention to one or more of these subjects, such as the American, New England and Central States Water Works Associations, the League of American Municipalities, the International Association of Municipal Electricians, etc., the question has often suggested itself whether there was need of so many kindred societies and whether better work could not be accomplished by a consolidation of some of them. It was true, he stated, that in the matter of water supply, street lighting, park development and the legislative functions of municipalities, excellent work was being done by other organizations; but upon the subjects of street paving, sewage, disposition of garbage and street cleaning, the papers and discussions of the annual conventions of this society comprised the most valuable contributions yet offered. He recommended that the question of co-operation or affiliation with societies having purposes in common with this be referred to the executive committee for consideration and recommendation to this convention.

The reports of Secretary George W. Tillson, of Brooklyn, and of Treasurer F. J. O'Brien, of Oswego, were then presented. The latter showed a total expenditure during the year of $568.80 and a balance on hand of $165.95.

The following resolution was submitted by Mr. Charles Carroll Brown, of Indianapolis, and referred to the executive committee: Whereas, The American Society of Municipal Improvements has learned with interest of a movement, started at the Boston meeting of the American Park and Outdoor Art Association last August, which looks to the ultimate alliance and co-operation of the various national societies now engaged in an effort to ameliorate civic conditions, and Whereas, such a movement, if generally participated in, and promising economy of administration with an increase of influence and authority, would have the cordial sympathy of this society, provided that no destruction were contemplated of the autonomy of each of the federating societies; therefore be it Resolved, that the American Society of Municipal Improvements appoint its retiring President, Edwin A. Fisher, as its representative on the national committee now forming for the consideration of the subject; and be it further Resolved, that he may, at his discretion, commit this society to such appropriation, pro rata to its annual income, as may be agreed to by the representatives of the other participating societies, toward the expense of the federation effort.

The report of the committee on "Uniformity in Municipal Accounting and on National Statistics" was next presented by the chairman, Charles Carroll Brown. With the exception of a few unimportant modifications, the forms recommended were the same as those which have been before the society for a number of years and have twice been printed in its proceedings. It was finally voted to adopt the forms which applied to streets and sewers, with the modifications suggested, and to accept and approve the blank form for water works adopted by the New England Water Works Association at its last meeting. It was also voted that this committee be instructed to collect municipal statistics and confer upon the subject with the Department of Labor at Washington.

The report of the committee on "Municipal Franchises," which was next in order, was not presented owing to the absence of Chairman Robert E. McMath, of St. Louis. It was announced that this report would appear in the printed proceedings of the convention. Mr. William S. Crandall, of New York, a member of this committee, submitted data bearing on this subject which had been secured by correspondence with mayors of fifty-three cities. The information obtained showed that several cities receive no compensation whatever from franchises granted to public corporations; others receive small amounts in the shape of a percentage of a state tax, an annual license on each street railway car or an annual tax on telegraph and telephone poles, while still others receive larger returns for the privileges voted to such companies. There was absolutely no uniformity in the manner in which different cities taxed their holders of franchises and the speaker thought this field an excellent one for investigation by the society.

At the Tuesday evening session several papers were read descriptive of Rochester and its public works. These were for the most part accompanied by stereopticon views. A paper on "Parks and Park Development" was read by Mr. G. A. Parker, Superintendent of Parks, Hartford, Conn. Resolutions on the death, which occurred Monday, of Mr. George A. Hotchkin, Superintendent of the Rochester Water Works and a member of the society, were read by Mr. Morris R. Sherrerd, of Newark, N. J., and were adopted. Mr. Hotchkin had prepared a paper on "Specifications, Testing, Installation and Care of Water Meters," which he was to have presented on Thursday. It was announced by President Fisher that this paper would appear in full in the report of the convention.

There was no session on Wednesday morning, the members being taken to points of interest in Rochester and to adjacent sections where roads are now being constructed by the state. The first business transacted at the afternoon meeting on Wednesday was the reading of a paper on "Municipal Sanitation" by Prof. A. Prescott Folwell, of Easton, Pa. This was in the form of a report of the committee on "Sewerage and Sanitation" of which Mr. Folwell is chairman.

A paper on "Residential Septic Tanks," by Mr. Burton J. Ashley, of Chicago, and one entitled "Practical Operation of Sewage Purification Plants," by Mr. John W. Alvord, of Chicago, were to have been presented at this session, but owing to the absence of these gentlemen it was voted to dispense with their reading and to print them in the published proceedings. Mr. John N. McClintock, of Boston, next read a paper on "The Biological System of Sewage Disposal." This was a description of the Glore system of bacterial sewage disposal. "Sewer Maintenance, under Whose Supervision and Why?" was the title of a paper presented by Mr. John H. Emigh, city engineer of North Adams, Mass. Mr. Emigh, as chairman of the committee on "Disposition of Garbage and Street Cleaning," also submitted a report which consisted of a contribution on the subject from Mr. Ernest Adam, city engineer of Newark, N. J., who had prepared statistics of the methods and cost of various systems employed by different cities in the United States.

The election of officers for the ensuing year was then taken up and resulted as follows: President, Charles H. Rust, Toronto, Canada; first vice-president, G. M. Ballard, Newark, N. J.; second vice-president, A. Prescott Folwell, Easton, Pa.; third vice-president, Edward D. Logsden, Indianapolis, Ind.; secretary, George W. Tillson, Brooklyn, N. Y.; treasurer, F. J. O'Brien, Oswego, N. Y.; finance committee, Emmet J. Steece, Burlington, Iowa, Frederick Giddings, Atchison, Kansas, and J. M. McCartin, Birmingham, Ala. Indianapolis, Ind., was chosen as the next place of meeting.

On Wednesday evening the members were given a banquet.

At the Thursday morning session Mr. Charles H. Rust, of Toronto, presented a report of the Committee on "Electric Street Lighting," of which committee he is chairman. This report consisted in part of statistics copied from Bulletin 4284 of the General Electric Co., giving the average hours per year, cost of coal per ton, contract price per lamp per year, cost to city per lamp per hour, and watts per hour per one cent in the different States. It was to be observed from this bulletin that the use of the enclosed arc lamp is rapidly supplanting the open lamp, and also that the use of the term "candle power" is replaced by the expression, "watts at lamp terminals." The Committee thought that franchises for street lighting should not be granted for too long a period, that wires in all large cities should be placed underground, lamp posts should be made of iron and of ornamental design, and that all work should be done under the direction of an electrician to be appointed by the corporation. Frequent tests should be made to ascertain if the lamps are giving the light provided for in the agreement. Municipal ownership of electric lighting plants was advocated by the Committee, but in case of private ownership, the city should receive a percentage of the gross receipts. A paper, entitled "Electric Street Lighting," by Mr. Alexander Dow, of Detroit, Mich., was read by Mr. Rust.

"The Economic Theory of Municipal Lighting" was the title of a paper which was to have been presented by Mr. Nicholas S. Hill, Jr., of New York. Mr. Hill sent word that it was impossible for him to attend the convention, but that he had prepared data upon this subject. It was voted to request Mr. Hill to forward this paper to the secretary of the Society, that it might be printed as a part of the proceedings of the convention. Mr. A. S. Hatch, president of the International Association of Municipal Electricians, was down for a paper on electrical government, but owing to the fact that the annual convention of that society is being held this week at Richmond, Va., it was not possible for him to attend this meeting. This paper will also be printed in the report of the convention.

A report of the Committee on "Water Works and Water Supply" was read by Mr. George H. Benzenberg, of Milwaukee, Wis. After referring briefly to the phases of waterworks development which have recently been the subject of the principal discussions in associations devoted exclusively to waterworks affairs, Mr. Benzenberg concluded his report as follows: "Another subject which has lately occupied the attention of waterworks associations is that of the preparation of standard specifications for cast iron pipe. The suggested form of specifications adopted by the New England Waterworks Association at its September meeting is a step in the direction of obtaining uniform joint dimensions in the manufacture of cast iron pipe and specials of different weights, but of same diameters, and is recommended for the consideration of the members of this association in the preparation of specifications for this class of work. No decided step, however, was taken towards improving the character of the pipe. In our opinion some modification of these specifications, particularly in regard to the method of cleaning the pipe and the character of the coating to be applied to the same, may prove of advantage and an investigation of this phase of the subject is suggested for the consideration of our successors on this Committee, who will probably also have the benefit of a trial of the standard specifications as adopted by the New England Waterworks Association. We are also of the opinion that the time has come when a much smoother interior surface of the pipe, possibly secured by vitrified coating, should be required; thereby improving the efficiency of the pipe system, as well as its permanent protection, and would suggest it as a subject worthy of the investigation of the new committee."

Mr. J. W. Howard, of New York City, read a paper entitled "Pavements Injured by Water; How to Minimize the Injury." He gave comparative data showing the amount of traffic in congested streets in some of the more important European and American cities. He pointed out that whereas the travel in certain streets in London, Paris, Berlin, etc., was greatly in excess of that in the busiest American thoroughfares, yet the pavements in these foreign cities often outwore many times those of American centers. This was due almost entirely to the manner of laying the material and of maintaining it, foreign cities taking into account more carefully the damaging effects of water. In the opinion of the speaker this was a subject of vital importance to all municipalities and he advocated the insertion in specifications for city pavements of a clause providing for water absorption and damage tests. He gave the results of tests made by himself showing the percentages of absorption of different paving materials, such as brick, trap rock, wood, asphalt, granite, etc. These amounts ranged from 0.85 to 30.10 per cent., certain stones showing the least and untreated wood the greatest degree of absorption.

The Thursday afternoon session was opened by the reading of the report of the committee on "Street Paving," by Mr. Nelson P. Lewis, of New York City, chairman. He was followed by Mr. Edward A. Bond, New York State Engineer and Surveyor, who described the "Work of the New York Highway Commission." Mr. W. E. McClintock, chairman of the Massachusetts Highway Commission, also spoke of the work being done under his supervision. He was followed by Mr. Emmet J. Steece, city engineer, of Burlington, Iowa, who read a paper entitled "Cost of Pavements and Roads in Small Towns." The remaining sessions of this very successful convention were to be held after this journal goes to press and it is therefore impossible to report their proceedings in this issue.

CONTRACTING NEWS

OF SPECIAL INTEREST TO

CONTRACTORS, BUILDERS, ENGINEERS AND MANUFACTURERS

OF ENGINEERING AND BUILDING SUPPLIES.

For Proposals see page xv, xvii, xviii and xxvii.

WATER.

Bridgeport, Conn.—The Bd. of Health has reported to the Bd. of Aldermen on the subject of filtration for the city's water supply; the estimated cost of sand filtration is given as about $26,000 per acre; 3½ acres would be required for a population of 70,000.

Newburyport, Mass.—This city is about to purchase 40 (6-in. streamer and 2 hose outlets) hydrants.

Gloucester, Mass.—The City Council has passed an order for the issue of $50,000 bonds for water mains in Annisquam, Bay View, Bass Rock, and other sections of the city, also an order for bonds to the amount of $310,000 to be expended as follows: $250,000 on Haskell's pond, $50,000 on a double pipe line to the city, and $10,000 plus premium not exceeding $10,000 on a pipe line from Dikes' meadow to the pumping station.

Norwich, Conn.—Press reports state that this city has decided to expend $45,000 in raising the dam at its reservoir.

Worcester, Mass.—The City Council Com. on Water has voted to recommend an order providing for the construction of a new dam on Mann's reservoir, on the Kettle brook system, at an estimated expense of $120,000.

Springfield, Mass.—Ex-Mayor N. D. Winter, Harlan P. Stone and O. M. Baker are stated to have been appointed as members of a special commission of citizens to investigate the whole problem of a better water supply for the city.

Pittsburg, Pa.—The Sub-Com. on Water Supply & Distribution has endorsed the ordinance which provides for additional 10-in. mains in the downtown district. Estimated cost $182,000.

Port Washington, L. I., N. Y.—A petition has been filed asking the Town Bd. for the establishment of a water supply district with street hydrants for fire protection.

Philadelphia, Pa.—Dir. of Pub. Wks. Haddock, Oct. 2, awarded the contract to construct preliminary filters at Lower Roxborough plant to the Maignen Filtration Co. for $49,800.

Hagerstown, Md.—It is proposed to organize a company with $25,000 capital to build a reservoir on the mountain at Pen-Mar, from which to supply the hotels and cottages at the resort. Geo. A. Finch, of Baltimore, Geo. W. Albaugh, of Westminster and Walter D. Wilson, of Hagerstown, are the prime movers in the project.

Syracuse, N. Y.—Local press reports state that work will soon be commenced by the Syracuse Rapid Transit Co. in the erection of a big basin at the power house to furnish water independent of the canal. A well will be sunk near the basin to furnish the water supply.

Allentown, Pa.—The estimated cost of constructing the new basin at Schantz's Spring is $15,000. The work includes 4,450 yds. of rock and 8,850 yds. of earth excavation.

Newark, N. J.—An appropriation of $20,000 has been granted for water extension for the new annexed district which was Clinton Township.

Black River, N. Y.—Jas. P. Brownell, of Carthage, has about completed a survey of Drake Creek, from which it is proposed to take water for the village system. The survey shows a daily flow of 750,000 gal.

Yonkers, N. Y.—The contract for furnishing and erecting a pump of 8,000,000 gal. capacity in 24 hours is stated to have been awarded to Henry R. Worthington for $25,800.

Oakland, Md.—H. G. Frederick, of Millersburg, Pa., has received from the Council a 25-year water works franchise.

Annapolis, Md.—See "Government Work."

Garfield, N. J.—Boro. Clk. F. E. Kane writes that it is proposed to construct water works, estimated to cost $40,000. Colin R. Wise, of Passaic, N. J., Engr. in charge.

Lancaster, Pa.—Improvements contemplated by the Susquehanna Water & Power Co., will not be made for some time, as property must be acquired and plans perfected, which will take several months.

Fultonville, N. Y.—The Fultonville Water Works Co. has been incorporated, with a capital of $300,000. David Gring, Pres.; J. D. Landers, Sec'y-Treas.

Mercersburg, Pa.—The Mercersburg Water Co., of Mercersburg, has been incorporated, with a capital of $20,000.

Savannah, Ga.—Bids are wanted Oct. 25 for a Corliss pump, pipes, valves, etc., as advertised in The Engineering Record.

Ft. McRee, Fla.—See "Government Work."

Richmond, Va.—Reuben Shirreffs, C. E., 219 E. Grace St., may give information regarding the proposed plan to furnish water from Swift Creek to this city by a company composed of John C. Robertson and others from Swift Creek.

Ft. Myer, Va.—Bids are wanted Oct. 20 for extending the water mains. Capt. W. F. Clark, Q. M.

Lancaster, O.—City Engr. John N. Wolfe writes that a vote is to be taken in Nov. on the proposition to issue bonds for water works improvements. Geo. Cunningham, Clk.-Sec'y to Water Wks. Trus.

Toledo, O.—Willis F. Brown, Law Bldg., Toledo, is making extensive surveys in connection with the special pure water commission, appointed to secure better water for this city.

Cleveland, O.—The contract for furnishing and erecting in boiler house at Kirtland St. pumping station, 6 water tube boilers has been awarded to Aultman & Taylor Machinery Co., Mansfield, O., for $37,495.

Chicago, Ill.—Bids are wanted Oct. 14 for constructing water service pipes. John A. May, Sec'y.

Somonauk, Ill.—An ordinance has been passed providing for the issue of $5,000 bonds for building a water tower.

Mineral City, O.—Bids will be received by the Bd. of Water Wks. Trus. until Oct. 27 for constructing the extension of the city water works system. W. F. Walter, Pres. of Bd.

Belleville, Ill.—The East St. Louis, Edgemont & Belleville Water Co., of Belleville, has been incorporated by M. M. Stephens, W. N. Horner and L. D. Turner. Capital, $2,500.

Truman, Minn.—It is stated that bids are wanted Oct. 14 for $5,800 water works bonds. O. N. Steenstrup, City Recorder.

Anderson, Ind.—The city is reported to be considering the matter of a better water supply; the question is whether deep water wells or filtered water from White River should be used. J. J. Netterville, Pres. Water Wks. Com.

Kiester, Minn.—Recorder C. W. Teubner writes that $5,000 bonds have been voted for water works. Geo. P. Hawley, Fairmount, Minn., is said to have been engaged to prepare plans for the proposed system.

Lima, O.—The City Council has passed the ordinance authorizing the issue of $150,000 water works reservoir bonds. Riggs & Sherman, of Toledo, have made surveys and estimates for proposed reservoir.

Burgin, Ky.—A stock company is reported as being organized here to establish water works. The company will have a capital of $14,000.

Lawton, Okla. Ter.—Bids are wanted Nov. 5 for constructing water works to include development of a supply, the construction of a storage reservoir, stand-pipe, pumping station and 9 miles of system pipe distribution. D. A. Jacobs, City Clk.; W. S. Shields, Designing Engr., Marquette Bldg., Chicago, Ill.

Sherman Heights, Tenn.—It is proposed to construct water works for this place; estimates not yet made.

Geary, Okla. Ter.—Bids will be received Oct. 27 for $27,000 bonds voted for the construction of a system of water works. J. M. Waterman, City Clk.

St. Louis, Mo.—Local press reports state that the Bd. of Pub. Improv. has voted to reject the filtration ordinance, and that the Water Com. has decided to try the plan of clarifying the water supply of the city by using alum to coagulate the sediment.

Miami, Ind. Ter.—W. L. McWilliams, Pres. of the Miami Artesian Water & Electric Light Co., writes that said company will receive bids about Nov. 1 for the construction of a system of water works, estimated to cost $30,000. Jas. K. Moore, Miami, Secy. of Co.; Thos. V. Hall, So. McAlester, Ind. Ter., Engr. in Charge.

Ft. Scott, Kan.—City Clk. J. O. Brown writes that no new franchise for water works will be granted until Jan. 1, 1903.

Ardmore, Ind. Ter.—The citizens are reported to have voted to issue $150,000 bonds for water works.

Johnson City, Tenn.—An amendment to the charter of the Johnson City Water Works Co., increasing its capital stock to $60,000, has been granted by the Secretary of State.

Leesville, La.—The stockholders of the Leesville Light & Water Works Co., Ltd., has decided to raise the capital stock from $40,000 to $100,000.

Medford, Okla. Ter.—Water works bonds to the amount of $25,000 are reported to have been sold.

Holdenville, Ind. Ter.—Bonds to the amount of $25,000 have been voted for a water works system.

Dallas, Tex.—The Council has approved the contract with Chester B. Davis, of New York City, to act as supervising and consulting engineer for the proposed water works improvements.

Lake Charles, La.—Press reports state this place proposes to construct a system of water works. Address May Poe.

Beaumont, Tex.—Geo. J. McManus, Gen. Mgr. of the McManus Irrigation Co., writes that it is proposed to irrigate, for rice, 2,100 acres, with 21 8-in. wells, 180 ft. deep, which flow above surface. Probable cost of engines, boilers, shafting, etc., 21 centrifugal pumps and fittings, $10,500, exclusive of wells, pipe and pits and housing. The incorporators of the company are: G. J. McManus, of Beaumont; A. E. McManus, of Duluth, Minn., and Chas. M. Lowe, 428 N. 1st St., Minneapolis.

W. F. Monahan, Dir. of the Texas Land & Irrigation Co., writes that it is proposed to construct an irrigation system.

Lexington, Miss.—A system of water works will be put in here at once to be owned and operated by G. W. Stigler and H. S. Hooker, of this town.

Purcell, Ind. Ter.—A franchise is said to have been granted to the Purcell Water Co. to put in a water system.

Decatur, Tex.—The City Council has made a contract with A. R. Whitehead, whereby it leased from him for a term of 5 years his water works plant.

Welsh, La.—S. A. Spencer and A. A. Shear, of Jennings, have made a proposition to erect an electric light, ice and water works plant for the town, provided the citizens would take $10,000 of the capital stock of the company, which is to be capitalized at $25,000.

Webster Groves, Mo.—Consulting Engr. Wm. H. Bryan, St. Louis, writes that the following bids were opened Oct. 6 for cast-iron pipe and special castings; prices are per net ton: Bidders—A, Am. Car & Fdy. Co., St. Louis Mo.; B, Dimmick Pipe Co., Birmingham, Ala.; C, M. J. Drummond & Co., New York; D, Chas. Miller & Son Co., Utica, N. Y.; E, U. S. C. I. Pipe & Fdy. Co., Chicago, Ill.; F, West St. L. Const. Co., St. Louis, Mo.; G, R. D. Wood & Co., Philadelphia, Pa.

	Cast-Iron Pipe

Golden, Colo.—Local press reports state that the City Council has rejected all bids for the construction of a gravity water works system and that new bids will be asked.

Montcloir, Colo.—The Town Council has under consideration a resolution which provides for the employment of an engineer to advise in regard to the proposed water and irrigation systems.

Phoenix, Ariz.—E. J. Bennett, J. C. Adams and others have been appointed a committee to investigate the advisability of establishing a city water works.

Denver, Colo.—Local press reports state that the Arkansas Valley Sugar Beet & Irrigation Co. proposes to build a dam 500 ft. wide and headgate for the Amity Canal. W. M. Wiley, of Holley, Colo., Mgr. of the Co.

Palo Alto, Cal.—Bonds to the amount of $40,000 are reported to have been sold to pay for extending the water and light system.

Crescent City, Cal.—The Crescent City Light, Water & Power Co. has been incorporated with a capital of $50,000. Incorporators: Nellie M. Duncan, T. B. Coulter and others.

Ft. Morgan, Colo.—Bonds to the amount of $40,000 are reported to have been voted for water works.

Mountainhome, Idaho.—Articles of incorporation of the Mountainhome Irrigation, Light & Power Co. have been filed. The corporation was organized in Utah and W. J. Turner has been appointed the resident agent of the Co. at Mountainhome. Capital stock $300,000. Geo. L. Nye of Salt Lake City, Pres.; W. J. Turner, of Mountainhome, Vice-Pres.; F. P. Sears, of Salt Lake City, Sec'y; A. G. Smith, of Mountainhome, Treas.

Lincoln, Neb.—The Elkhorn Valley Irrigation Co. has incorporated with a capital stock of $300,000. The incorporators are F. M. Widner, of Corning, Ia., and T. G. Foster, H. S. Rand and E. S. Huston, all of Burlington, Ia.

Randsburg, Cal.—The Evergreen Land & Water Co. has been incorporated. Principal place of business, Randsburg. Directors: G. W. Lloyd, C. G. Dillingsworth, G. J. McDivitt and others. Capital stock, $500,000.

La Habra, Cal.—The La Habra Water Co. has been incorporated. Directors: Geo. Chaffey, Edw. Records, O. L. Baldwin, C. W. Gould, W. W. Stowell. Capital stock, $300,000.

Greeley, Colo.—The proposition to issue $200,000 bonds for a mountain water supply for the city, will probably be voted upon by the people.

Searcy, Ark.—This city will build a system of water works and an electric light plant to cost $30,000. Estimates, plans and specifications are being prepared. The work is in the hands of a local Bd. of Improvement composed of P. A. Robertson, Chmn.; Emmet Snipes, Sec'y, and Henry Patterson. Owen Ford, Consulting and Supervising Engr., 710 Security Bldg., St. Louis, Mo.

De Smet, S. D.—City Aud. J. C. Gibson writes that on Sept. 27 bonds to the amount of $13,500 were voted for water works and $6,500 bonds were voted for gas lighting; the City Council will receive bids on Oct. 27 for the sale of said bonds.

Brigham City, Utah.—Bids are wanted Oct. 14 for constructing about 5,700 ft. of 30-in. wooden stave pipe for a water power plant in Box Elder Creek Canyon. Heber C. Boden, Mayor.

Lidgerwood, N. D.—W. I. Gray & Co., of Minneapolis, have secured the contract for the water works plant complete, at $8,865. J. J. Flatcher, Engr., Minneapolis, Minn.

Bremerton, Wash.—See "Government Work."

Denver, Colo.—The Farmers' Reservoir & Irrigation Co. has been incorporated, with a capital of $1,000,000 by Jos. Standley, of the Adams Hotel, Milton Smith, an attorney, and others.

Hamilton, Ont.—Bids are wanted Oct. 31 for boring an artesian well or wells to furnish the Insane Asylum a daily supply of about 70,000 gals. of water. R. Christie, Inspector of Prisons and Pub. Charities, Toronto.

SEWERAGE AND SEWAGE DISPOSAL.

Hudson, Mass.—Town Clk. D. W. Stratton writes that the proposition to construct a sewerage system has been referred to a committee for investigation.

Medford, Mass.—The Comrs. of Sewers have ordered the construction of a common sewer on Grove St., to be built under the direction of City Engr. Wm. Gavin Taylor.

Westfield, Mass.—Local press reports state that Town Engr. O. E. Parks is receiving bids for the construction of the southerly section of the surface drainage system.

Boston, Mass.—The following bids were opened Oct. 1 by the Metropolitan Water and Sewerage Bd. for building Section 45 of the High-Level Sewer in Quincy: A, Harry P. Nawn, Boston, $90,350; B, John Cashman, Quincy, Mass., $78,110; C, E. W. Everson & Co., Providence, R. I., $71,930; D. Wm. H. Ellis, Boston, $71,620; E, Latta & Terry Co., 801 Drexel Bldg., Philadelphia, Pa., $68,372 (awarded). For detail bids see accompanying table.

Bidders.	Rock or earth excav. and refill. 135"x150" sewer. 970 Lin. Ft.	Brick Mas. Portland. 600 Cu. Yds	Concrete Mas. American. 100 Cu. Yds.	Concrete Mas. Portland. 3,500 Cu. Yds.
A	$50.00	$19.00	$7.00	$8.50
B	38.00	18.00	7.00	8.50
C	39.00	15.00	6.00	7.00
D	36.00	17.50	6.50	7.30
E	30.10	16.50	7.50	8.15

Bids received at the same time for Section 78 High-Level Sewer in Roxbury: E. W. Everson & Co., $34,750; Latta & Terry Co., $27,930; H. P. Nawn, $24,340; Metropolitan Cont'g Co., $23,637; C. E. Trumbull & Co., $23,390; H. A. Hanscom Co., $22,690; Patrick McGovern, $18,360; Chas. Linehan, $17,820. The contract was awarded to Patrick McGovern, Boston, at his bid, which was as follows: Earth excavation and refilling in trench, 78x84-in. sewer, 600 lin. ft., $9; brick masonry, American, in trench, 100 cu. yds., $13; brick masonry, Portland, in trench, 450 cu. yds., $14; concrete masonry, American, in trench, 100 cu. yds., $6; concrete masonry, Portland, in trench, 400 cu. yds., $7; spruce piles in place, 7,000 lin. ft., 22 cts.; spruce lumber in trench in place, 12 M. ft. B. M., $35.

Erie, Pa.—Ordinances are being introduced in the councils for an extensive intercepting sewer system.

Scranton, Pa.—Ch. Engr. Jos. P. Phillipa writes that the contract for constructing sewers in the 19th Dist. has been awarded to Ruch & Miller, 1345 Arch St., Philadelphia, their bid being as follows: Sewer complete with stone cover basin and full lining in tunnel, at $2.88 per lin. ft.; sewer complete with Pierce or other casting covered basins and full tunnel lining, at $2.77¾ per lin. ft. (accepted); extra basins (stone cover) $95 each; extra basins (casting cover) $65 each; extra manholes, $50 each; extra house connection, 50c. per lin. ft.; tunnel arch lining, $2.75 per lin. ft. The work includes 64,805 ft. of 8-in. to 63-in. pipe and brick sewers with 364 manholes, 165 catch basins, and 26,100 ft. of 6-inch pipe house connections; the trench to average 11 ft. in depth and be excavated 20 per cent. in rock and 80 per cent. in earth. Bids were opened for above work on Oct. 6 by Dir. of Pub. Wks. John E. Roche.

Millburn, N. J.—Bids are wanted Oct. 20 for building a sewerage system for this township, as advertised in The Engineering Record.

Binghamton, N. Y.—Bids are wanted Oct. 28 for the construction of a sewer in De Forest St., also for a sewer in Green St. I. C. Hull, City Clk.

Lancaster, Pa.—The City Council has passed an ordinance appropriating $15,563 for sewers and macadamizing.

Patchogue, L. I., N. Y.—Sewer bonds to the amount of $10,000 were sold by the Village Trus., Oct. 8.

Allentown, Pa.—Local press reports state that bids will be received by the Mayor until Oct. 21 for constructing a sewer on portions of Allen St.

Avalon, N. J.—Bids are wanted Oct. 17 for furnishing materials and laying about 5,000 ft. of terra cotta sewer pipe. Gilbert S. Smith, Mayor.

Oneida, N. Y.—City Engr. Vedder has prepared plans for 2 8-in. sewers on West St.

Philadelphia, Pa.—The Bd. of Health has recommended that the City Council make appropriations for the immediate construction of sewers in Dickinson, Greenwich, Flora, Etting and De Kalb Sts.

Niagara Falls, N. Y.—The contract for constructing Chasm Ave. tunnel trunk sewer has been awarded to W. W. Read & Co., for $22,891.

Phoenixville, Pa.—The Town Council is considering an ordinance which provides for the construction of sanitary sewers.

Corinth, N. Y.—The Bd. of Health has recommended that sewers be extended on Main St.

New Castle, Pa.—The Council has passed bills providing for the construction of sewers on several streets.

Newark, N. J.—The contract for constructing Section 4 of the Joint Outlet Sewer, has been awarded to John P. Hall, of Jersey City, for $47,553.

Brooklyn, N. Y.—Bids are wanted Oct. 29 for constructing sewers in proposed street through northern portion of Dyker Beach Park and in 92d St.; the engineer's estimate calls for brick sewers 159-in. to 30-in. in diameter, vitrified stone water pipe sewers, 24-in. to 12-in. in diameter, with 65 manholes, 26 catch basins, planking, sheeting, etc. Amount of security required $335,000. J. Edw. Swanstrom, Comr., Pres. Boro. of Brooklyn.

Cape Charles, Va.—City Clk. I. J. Burbage writes that the Town Council intends to put in a sewerage system this fall, at a probable cost of $7,000.

Ft. McKee, Fla.—See "Government Work."

La Grange, Ga.—The following bids were opened Sept. 29 for the construction of 49,300 ft. of 6 to 18-in. pipe sewers, with 96 manholes and 18 flush tanks; the trench to average 7½ ft. in depth and be excavated in clay and loam. Roy Dallis, of La Grange, Engr. Bidders: A, Williams & Wadley, Macon, Ga.; B, A. L. Patterson & Co., Durham, N. C.; C, Geo. W. Waring, Columbus, S. C.; D, W. H. Harris & Co., Jacksonville, Fla.; E, Thos. Wagner, Mobile, Ala.; F, Howard Neely, Chattanooga, Tenn.; G, Frederic Minshall, Greenwood, S. C.; H, W. C. Porter, Greenville, Miss.; I, Moore & McCrary, Atlanta, Ga. (awarded at a total of $21,196); J, R. E. Boggs, Spartanburg, S. C.

Warsaw, N. Y.—City Clk. C. H. Hain writes that on Sept. 29 it was voted to issue bonds for repairing streets and improving the sewerage system.

Corning, N. Y.—City Clk. E. J. Kelly writes that the proposition to install a sewerage system in the Fifth Ward, at a cost of $30,000, is under consideration, pending the engineer's report.

Newark, N. J.—Local press reports state City Surveyor Adam has been authorized by the Bd. of Wks. to perfect and put into operation plans for working out the Badger Ave. sewer problem.

Newark, N. J.—An addition of $43,000 is to be made to the $600,000 the city has agreed to pay as its share of the cost of elevating and depressing the Lackawanna R. R. tracks on account of the sewer that is to run inside the railroad retaining wall from Morris Canal west through Roseville to the city line.

Ironton, O.—City Engr. J. R. C. Brown writes that the contract for 18 and 12-in. sewers, with 34 manholes, in Dist. No. 4, has been awarded to I. B. Black, of Ironton, for $6,054.

Cincinnati, O.—Local press reports state that the various villages, interested in the proposed construction of a sewer through Mill Creek Valley, from Glendale to the Ohio River, through a committee appointed from their various Bds. of Health, have turned the entire matter over to the State Bd. of Health, and that body is now having the creek surveyed.

Elkhart, Ind.—Bids are wanted Oct. 22 for the construction of a sewer in Crawford, Christiana and other streets. Emil V. Anderson, City Clk.

Wabash, Ind.—Bids are wanted Oct. 27 for the completion of the local sanitary sewer in Main St. Fremont McLees, City Clk.

Cleveland, O.—Bids are wanted Oct. 16 for the reconstruction of a culvert across Woodland Hills Ave.; bids are also wanted Oct. 30 for the construction of a sewer in Petrie St. Chas. P. Salen, Dir. of Pub. Wks.

Toledo, O.—Bids are wanted Oct. 20 for constructing a circular brick sewer 24-in. inside diameter and a 12-in. pipe sewer in the alley between Walbridge Ave. and Colton St. Chas. H. Nauts. City Clk.

Indianapolis, Ind.—Bids will be received by the Bd. of Co. Comrs. until Oct. 18 for constructing a sewer at the Co. Poor Asylum. John E. McGaughey, Chmn. Comrs.

Dayton, O.—Robt. H. Ferguson, City Compt., writes that the lowest bid received Oct. 3 for the construction of sewers in 4 streets, was from Wm. Hilt of Dayton, at a total of $5,090.

Des Moines, Ia.—Bids are wanted Oct. 17 for constructing an 8, 9 or 12-in. sewer from the McKinley school to Des Moines River. Theo. F. Grefe, 219 4th St., Chmn. Com. on Bldgs. and Grounds.

Columbus, O.—Local press reports state that contracts are about to be let for the construction of the West Side main trunk sewer system.

Pendleton, Ore.—The City Council is reported to be considering the construction of a sewerage system.

St. Louis, Mo.—Bids are wanted Oct. 14 for constructing pipe sewers in N. 2d St. and in Clarendon Ave., Sewer Dist. No. 5. Hiram Phillips, Pres. Bd. of Pub. Improv.

Lake Charles, La.—Parish Surveyor John W. Rhorer writes that plans and estimates are now being received for the proposed sewerage system; it is the intention to order an election for a bond issue after estimates are in. John H. Poe, Mayor.

Birmingham, Ala.—The City Council has passed an ordinance providing for the construction of storm water sewers in the vicinity of Ave. H and 12th St. Estimated cost, $26,000.

Nashville, Tenn.—It is stated that bids are wanted Nov. 6 for constructing a 9 to 11-ft. brick sewer about 1 mile in length, requiring about 17,000 cu. yds. excavation and 5,000,000 brick. Wm. W. Southgate, City Engr.

Ensley, Ala.—The citizens are stated to have voted on Oct. 6 to issue $75,000 bonds for a sewerage system.

Rapid City, S. D.—Bids are wanted Oct. 23 for furnishing material for constructing an extension to the Rapid City School sewer system. Address W. A. Jones, Comr. of Indian Affairs, Washington, D. C.

Seattle, Wash.—Bids will be received by the Co. Bd. of Drainage Comrs. until Oct. 25 for furnishing material for constructing drainage ditches in drainage Dist. No. 1. Robt. Bridges, Chmn.

Toronto, Ont.—City Engr. C. H. Rust writes that the proposed separate sewerage system for the East End Dist. is estimated to cost about $50,000.

St. Boniface, Man.—Cass & Couture are stated to have secured the contract for constructing sewers on La Verandyre St. for $7,494.

BRIDGES.

Hooksett, N. H.—The Manchester Electric Co. (C. H. Farrell, Supt., Manchester) will replace the wooden bridge over its canal at Hookset, with an iron structure.

Boston, Mass.—The following bids were opened Oct. 3, and taken under advisement, for building six masonry piers at the Atlantic Ave. bridge: Bidders all of Boston: Lawler Bros., $58,794; W. H. Ellis, $69,700; Holbrook, Cabot & Rollins, $73,500; Patrick McGovern, $74,900; Jones & Meehan, $75,800; Wm. L. Miller, $84,618; Norcross Bros., $112,300.

The following bids for the steel superstructure of sections A and B of the Broadway bridge were opened Oct. 8, at the office of the City Engr.: Section A includes that portion of bridge on South Boston side of Fort Point channel, extending from Foundry St. abutment to the draw span, and will consist of 14 plate girder and I-beam spans having a total length of about 574 ft., measured along center line, and a width of 60 ft. between street lines. Section B includes that portion of bridge on Boston side of Fort Point channel between the draw span and the Lehigh St. abutment; it will consist of 6 deck plate girder and I-beam spans, having a total length on center line of about 338 ft.: Boston Bridge Wks., Boston, $112,874; King Bridge Co., Cleveland, O., $119,500; Variety Iron Wks. Co., Cleveland, O., $119,000; Canton Structural Co., Albany, N. Y., $130,000; American Bridge Co., New York City, $123,300; W. H. Keepers & Sons, Portsmouth, N. H., $121,950; Berlin Const. Co., Berlin, Conn., $128,000; Eastern Bridge & Structural Co., Worcester, Mass., $116,450; New England Structural Co., Boston, $113,900. The bids were taken under advisement. The contract calls for the completion of the work on or before Oct. 1, 1903.

Binghamton, N. Y.—State Supt. of Pub. Wks. Chas. S. Boyd has awarded the contract for constructing a bridge over Erie Canal at James St., to the Owego Bridge Co., Owego, N. Y., for $17,445.

Meadville, Pa.—The middle span, 130 ft. long, of the Erie Ry. bridge over French Creek, at Buchanan Junction, is reported to have collapsed Oct. 5.

Principio, Md.—Press reports state that the Pennsylvania R. R. has decided to replace the culvert at Principio, on the Phila., Baltimore & Washington Div., with a large stone arched bridge. Jos. T. Richards, Engr. Maintenance of Way, Philadelphia.

Northeast, Md.—Cecil Co. Comrs., Elkton, have accepted an offer of the York Bridge Co. to prepare plans for new masonry and an iron superstructure 120 feet long, with 18 ft. driveway and a 6 ft. walk on either side, over North East Creek at Northeast.

Reading, Pa.—The County Comrs., Engr. Dreibelbis and Bridge Inspector Moser have visited Sunday's mill to inspect the site for the bridge over the Tulpehocken connecting Jefferson and North Heidelberg townships.

A bridge about 600 ft. long is to be built in the lower section of the city to extend over 2 railroads and the Schuylkill River.

New Castle, Pa.—It is proposed to build a county bridge 264 ft. wide to connect West Pittsburg and Cascaskee. Estimated cost $20,000.

Erie, Pa.—City Clk. F. Hanlon writes that the city of Erie, the Erie Electric Motor Co., and the P. & E. R. R. Co., are considering the proposition to jointly construct a $54,000 bridge over Buffalo road crossing.

Harrisburg, Pa.—W. H. Brown, Ch. Engr. Pa. R. R. Co., Philadelphia, writes that the work of building a subway under the tracks at Herr St., has not yet been placed under contract.

Hempstead, L. I., N. Y.—A bridge to cost $8,000 is to be built across the track at the West Hempstead grade crossing, the L. I. R. R. and the Mineola, Hempstead & Freeport Traction Co. having agreed to divide the expense.

Sullivan, Ind.—Bids are wanted Oct. 24 by the Bd. of Comrs. Vigo and Sullivan counties for constructing Allen bridge, 50 ft. span, 14 ft. roadway, and Dwyer bridge, 40 ft. span, and 14 ft. roadway. J. M. Laug, Aud. Sullivan Co.; Jas. Soules, Aud. Vigo Co.

Shelbyville, Ind.—The Bd. of Co. Comrs. will receive bids Oct. 18 for the construction of an iron bridge over Dry Fork.

Indianapolis, Ind.—Bids are wanted Oct. 16 for constructing the east approach to bridge over White River at Crow's Nest. Harry B. Smith, Aud. Marion Co.

Bids will be received by the Bd. of Co. Comrs. until Oct. 18 for constructing a bridge over Lick Creek. John McGregor, Chmn. Comrs.

The Bd. of Wks. has been informed by the Big Four R. R. that it will begin immediately the construction of a new viaduct over its tracks at Noble St.

The Bd. of Pub. Wks. has decided that it will be impossible to repair the Pleasant Run bridge at Ohio St., and a new bridge will probably be built in the near future.

Oshkosh, Wis.—The Council has made an appropriation for plans to be prepared by Erickson & Lehman for a 60-ft. span bridge to cross Sawyer Creek.

Detroit, Mich.—The Michigan Central, the Lake Shore and Grand Trunk R. R.'s are said to be considering the construction of a bridge across the tracks at Junction Ave.

Welch, Minn.—The contract for building a bridge across Vermilion River has been let by the Bd. of Co. Comrs. and the Town Bds. of Welch and Burnside to W. E. Hewitt & Co., of Minneapolis, for $5,100.

Youngstown, O.—To relieve congestion of traffic at the Holmes St. and North Ave. crossings of the Erie R. R., plans have been prepared for a viaduct to cross the tracks. Cost for superstructure about $75,000, the major portion of the expense to be borne by Erie R. R. and Mahoning Valley Electric Ry.

Wooster, O.—Co. Comr. Harrison estimates that it will cost $8,000 to repair bridges destroyed by recent storm.

Columbus, O.—The County Comrs. have ordered plans for the bridges to be built on the Taylor road in Madison township over Big Walnut and Alum Creeks. One bridge is to be 216 ft. long and the other about 148 ft. long.

Brazil, Ind.—By the terms of a recent agreement the Vandalia R. R. Co. is to build a steel bridge 100 ft. span across Birch Creek on the line dividing Sugar Ridge and Jackson township, and the Bd. of Co. Comrs. is to build a steel bridge, 60 ft. span, on the highway located 1 mile south of Hoosierville.

Minneapolis, Minn.—It is stated that bids will be received by the Co. Comrs. until Oct. 20 for rebuilding 6 county bridges. Hugh R. Scott, Co. Aud.

Lawton, Okla. Ter.—The Canton Bridge Co., of Canton, O., has received the contract for constructing 5 bridges at prices ranging from $2,000 to $5,000.

Cordova, Ala.—Bids will be received by the Co. Comrs. until Nov. 5, for constructing a steel bridge over Cone Creek. J. W. Shepperd, Judge of Probate.

Austin, Tex.—Local press reports state that work will soon be started on the bridge to be built across Colorado River at Austin for the International and Great Northern R. R. A. L. Bowers, Supt. of Const., and J. D. Trammel, Ch. Engr., Palestine, Tex.

Berclair, Tex.—The iron bridge over Miller's Creek, belonging to Goliad County, is reported to have been swept away by floods.

Beeville, Tex.—Local press reports state that the Southern Pacific R. R. Co.'s steel bridge over the Blanco River has been destroyed by floods.

St. Louis, Mo.—Local press reports state that bids will be received Oct. 24 by the Bd. of Pub. Wks. for the superstructure work on the 18th, 21st and Grand Ave. bridges.

Lexington, Neb.—The proposition to issue bonds for the construction of a bridge across Platte River was carried. Address the County Clk., Lexington.

San Francisco, Cal.—See "Railroads."

Marysville, Cal.—Local press reports state that the Southern Pacific R. R. engineers have concluded the preliminary work looking to the construction of a steel railroad bridge across Feather River at Marysville, and also of a bridge to cross Sacramento River at Knight's Landing.

PAVING AND ROADMAKING.

Killingly, Conn.—Highway Comr. Macdonald has awarded to the town of Killingly contracts for improving the following roads in said town: A section of gravel on Elmsville road at 45c. per lin. ft.; a section of gravel on Williamsville road at 65c. per lin. ft., and a section of macadam on Five Mile road at $1.20 per lin. ft. About 6,000 ft. of highway is to be improved at a cost of $5,200.

Reading, Mass.—The State Highway Comrs. have awarded to Ferranti & Maguire, of Worcester, the contract for building a state road in Reading, for $6,334.

Warsaw, N. Y.—See "Sewerage and Sewage Disposal."

Cohoes, N. Y.—Local press reports state that the Pub. Improv. Com. has awarded the contract for paving alley between Congress and Lancaster Sts., with sheet asphalt, to the Barber Asphalt Paving Co., at $2.35 per sq. yd. Bids for paving Rock alley will be received Oct. 15.

Newton, N. J.—Bids are wanted Oct. 20 by the Bd. of Chosen Freeholders of Sussex Co., for macadamizing sections of the following roads: Sparta and Newton road, Stanhope and Newton road, also Sussex and Newton road. A. H. Konkle, Co. Engr., Newton. Emmett H. Bell, Dir. Bd. of Chosen Freeholders.

Philadelphia, Pa.—Bids are wanted Oct. 14 for grading, repaving, etc., portions of several streets, also for repaving country roads with broken stone. Wm. C. Haddock, Dir. Dept. of Pub. Wks.

Brooklyn, N. Y.—The Bd. of Estimate on Oct. 6 authorized the paving with granite block of Nostrand Ave., from Malbone St. to Flatbush Ave., at a cost of $123,300, and of Rogers Ave., between the same Sts., at a cost of $109,600.

West Hoboken, N. J.—Demott St. property owners have petitioned the Council to reject all bids for bituminous macadam paving on that street, the lowest bid, which was $19,430, being considered excessive.

Pittsburg, Pa.—Bids for paving numerous streets with asphalt were opened Oct. 1, the lowest bid having been received from the Pittsburg Asphalt Co., at prices ranging from $1.79 to $1.95 per sq. yd.

New York, N. Y.—Bids are wanted Oct. 14 for regulating and repaving with asphalt and granite, on present pavement and concrete foundation, the roadway of Park Ave., from 111th St. to 133d St.; estimated quantities—61,200 sq. yds. of asphalt pavement, including binder course; 2,400 sq. yds. granite block pavement; 61,500 sq. yds. of old stone pavement relaid as foundation; 7,600 lin. ft. old blue stone curbstone, etc. Bids are also wanted at the same time for 3,190 sq. yds. of asphalt pavement in 117th St., from 5th Ave. to Lenox. Jacob A. Cantor, Boro Pres.

Atlantic City, N. J.—County Engr. J. J. Albertson, Magnolia, N. J., writes that the following bids were opened Oct. 1, for constructing the proposed elevated gravel road across the meadows, between Pleasantville and Atlantic City, a distance of about 4 miles, to include bulkheading, bridging and pumping sand for filling: John B. Hess & Co., Atlantic City, $83,306 (awarded); The Construction Co., Atlantic City, $124,000.

White Plains, N. Y.—Bids are wanted Oct. 14 for furnishing all material and labor to lay a 4-ft. flag walk, set stone, pave and curb gutters in numerous streets and avenues. Peter Paulding, Village Clk.

Washington, Pa.—The Boro. Council has sold street improvement bonds to the amount of $150,000.

Lancaster, Pa.—See "Sewerage and Sewage Disposal."

Buffalo, N. Y.—Bids are wanted Oct. 21 for paving portions of Hamburg Turnpike 36 ft. wide; also for repaving portions of Louisiana St. Francis G. Ward, Com. Pub. Wks.

Petersburg, Va.—Local press reports state that this city contemplates expending about $100,000 for further improvement of the streets; it is believed that brick or asphalt will be used.

Connersville, Ind.—City Engr. Karl L. Hansen writes that contracts for sidewalks, etc. (bids opened Oct. 1) have been awarded to Chas. & Roy Williams, of Connersville, as follows: 125,000 sq. ft. of cement walk at 8.7c. per sq. ft.; 4,000 lin. ft. curb and gutter, at 64c. per lin. ft.; 500 ft. 12-in. sewer, at 70c. per ft.
